HEALTH, STRENGTH, AND ENERGY.

DR. LALOR'S PHOSPHODYNE.

(Trade Mark—Phosphodyne.)

TWENTY YEARS' PUBLIC TEST, AND THOUSANDS OF TESTIMONIALS FROM

ALL PARTS OF THE WORLD ESTABLISH

PHOSPHODYNE

as the only Safe, Reliable, and Never failing Phosphoric Remedy for Over-worked Brain, Sleeplessness, Harassing Dreams, Worry, Anxiety, Excitement, Epilepsy, Business Pressure, Wasting Diseases, Nervous Prostration, Stomach and Liver Complaints, Impoverished Blood, Premature Decay, and all morbid conditions of the system dependent upon the deficiency of the Vital Forces.

DR. LALOR'S PHOSPHODYNE PURIFIES AND

Enriches the Blood, Clears the Skin, thoroughly invigorates the Brain, Nerves and Muscles, Re-energises the Failing Functions of Life by supplying the Phosphoric element which has been wasted, and thus imparts Energy and Fresh Vitality to the Exhausted Nerve-Electric Force, and rapidly Cures every form of Nervous Debility, Paralysis, Kidney, Nervous, Mind, and Heart Diseases, from whatever cause.

This elegant Phosphatic combination, the Wonder of Modern Chemistry, is pronounced by the most eminent members of the Medical Profession to be unequalled for its power in replenishing and elaborating the Vitality of the Body; by its supplying all the essential and vitalising constituents of the BLOOD, BRAIN, and NERVE SUBSTANCE; and for developing all the Powers and Functions of the System to the highest degree; by its being agreeable to the palate, and innocent in its action. While retaining its wonderful properties, it acts as a Specific, surpassing all the known THERAPEUTIC AGENTS of the PRESENT AGE, for the SPEEDY and PERMANENT CURE of the above disease.

DR. LALOR'S PHOSPHODYNE is sold in Bottles at 4s. 6d. and 11s. 6d. and Retail Medicine Vendors

IMPORTANT NOTICE.—NONE IS GENUINE UNLESS the name, Dr. Lalor's Phosphodyne, London, England, is blown in the Glass of each Bottle, and every Bottle bears the British Government Stamp, with the words DR. LALOR'S PHOSPHODYNE, London, England, engraved thereon by Order of Her Majesty's Honourable Commissioners; IF NOT, IT IS A FORGERY, AND YOU HAVE BEEN IMPOSED UPON BY A WORTHLESS IMITATION.

MANUFACTURED ONLY AT THE

The following Tests by Kirk

From 13 in. to
1 America.

length and value,

| | Strain per Square Inch of Section. | Price per foot. |
|--|------------------------------------|-----------------|
| Best Double Leather 6 in. Belting | 3,877 lbs. | 5s. 7d. |
| Gandy's 1 1/2 in. x 8-ply Cotton | 6,811 lbs. | 2s. 6d. |

THE GANDY BELT.

Any Length or Width
for Main Driving.

It is the best belt
ever made for all purposes.
Much Cheaper and
Stronger than Leather.
Thoroughly Waterproof,
and not affected by temperature,
clings well to the pulleys,
runs true, and can be made
any length without joints.

This Series of Belting
(see engraving) was supplied
in One Order to Messrs. John
Crossley and Sons, Halifax, May
1, 1880, and continues to give
entire satisfaction.

THE "GANDY" BELT.

GANDY'S Patent American Cotton Belting can claim a superiority over leather belts in every particular; its cost being about half that of leather, while its strength and gripping power is about double that of the best leather, as shown by repeated tests taken by Kirkaldy, of London. These tests are given above, to which special attention is directed. These "Gandy" belts are made of any width up to 72 inches, and any length up to 340 feet without joint, thus obviating the necessity of having two belts on the same pulley, a system of driving which is never satisfactory, as it is impossible to have belts of exactly the same tension; hence one or the other is always causing a stoppage. These stoppages are avoided by using Gandy's Patent Belts in one width. These Gandy Belts are made of the finest American Cotton Duck, specially prepared at Baltimore for the purpose, and then put together by Gandy's patented special Machinery and process to prevent stretching, and render them impervious to atmospheric influence. Possessed of advantages such as these, the universal adoption of Gandy's Belts can only be a question of time.

A SUBSTANTIAL GUARANTEE GIVEN WITH EVERY MAIN DRIVING BELT.

MAURICE GANDY,

FIRE BRICKS.

RANEENGUNGE FIRE BRICKS as supplied to Government and
the various Railways, Iron Works, Coal, Gas, and Steam
Navigation Companies. Price—Rs. 9 per 100.

Extract from Official Report of tests made at H. M.'s Mint,
Calcutta, by THEODORE W. H. HUGHES, Esq., F.R.S., A.R.S.M., Offi-
ciating Deputy Superintendent, Geological Survey, India:—

"The Fire Bricks tested by me were furnished by the Firm of
Messrs. BURN & Co. * * * The materials from which they are made
are very refractory and capable of resisting high temperature with-
out sensibly fusing. * * * That compared with Stourbridge Fire
Bricks are somewhat superior."

The specimens were subjected to a temperature of over 3,000
degs. Fahr., the smelting point of Cast-iron being 2,786 degs.
Fahr.

THE INDIAN AGRICULTURIST.

A MONTHLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. VIII.] CALCUTTA :—MONDAY, JANUARY 1, 1883.

[No. 1.]

NOTICE.*

SUBSCRIBERS to the STATESMAN, FRIEND OF INDIA, and INDIAN AGRICULTURIST are informed that arrangements have now been made by which these journals will for the future be published under the general superintendence of the undersigned.

All communications concerning the general business of the STATESMAN AND FRIEND OF INDIA Office, Advertisements, and Subscriptions to the daily STATESMAN AND FRIEND OF INDIA, weekly FRIEND OF INDIA AND STATESMAN, and INDIAN AGRICULTURIST, should be addressed to the **MANAGER**.

All communications regarding literary matter should be addressed to the **EDITOR** of the paper for which it is intended.

WILLIAM RIACH.

June 13th, 1881.

CORRESPONDENCE.

CAWNPORE EXPERIMENTAL FARM.

TO THE EDITOR.

SIR,—Will you permit me to offer a few remarks on the scathing strictures passed by Mr. O. L. Bryce in re Mr. Fuller's experiments at Cawnpore ?

I must first state I am not an agricultural analytical chemist, but an amateur, and secondly, that I have never met Mr. Fuller ; he comes from the N.-W.P., whereas I hail from another part of India, so that you can acquit me of having any personal feelings in the controversy.

Mr. Fuller's lips are sealed by official etiquette, but I am not so restricted—

“ Which is why I remark

“ And I own it with pain—

That there is nothing in Mr. Fuller's report to show the operations were conducted with want of care ; moreover, I fail to see that any analysis of either farmyard manure, or the superphosphate employed, could have been productive of any real good. Any chemist, or in fact any man who had any theoretical knowledge of *agricultural analytical chemistry*, could, knowing the quality of the ingredients employed, be able to calculate, within very narrow limits, the composition of his superphosphate, i.e.—the quantities of calcic sulphate, alkaline salts, calcic phosphate, &c., contained therein. With regard to the state of the manure (farmyard dung) used, if Mr. Fuller did not state whether it was rotted or not, he evidently concluded, as I do, that no man in possession of his senses would, without very good reason, use other than thoroughly decomposed dung.

Again, Mr. Bryce says that Mr. Fuller's experiments have not resulted in any improvement of the staple. This is a sweeping assertion unsupported by specific proof, for the very fact of the pedigree wheat having given such a large yield, in some instances equal to 4 bushels per acre, shows that under Mr. Fuller's management the quality of the grain has improved.

Mr. Bryce again twits Mr. Fuller about the absence of analysis year by year. This is mere hair-splitting, and it is not unreasonable to suppose that, having increased in productive powers, it may to a slight extent have increased in albumenoids and carbon hydrates, as any other wheat would have done. Surely Mr. Bryce,

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bighah in particular varies so much in the different provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

as an agricultural analytical chemist, must know that to improve a staple of any kind is a process demanding some years of careful cultivation. Three years is a very limited period, and should the Department of Agriculture succeed in raising a species of wheat to the English or European scale of productiveness in even six years, a great deal will have been done. Nature does not move by "leaps and bounds." American maize, Carolina rice, New Orleans cotton were not brought up to their present standard of excellence in a single decade.

According to Mr. O. L. Bryce, Mr. Fuller's great fault rests in the fact of his not being an *agricultural analytical chemist*, but merely a poor man, an official of considerable ability, who, in addition to having received a liberal education and possessing a natural predilection for agricultural pursuits, brings a mind enlarged by experience in India to assist him in the discharge of his duties. It was no doubt on these grounds that the Government saw fit to transfer him to the Central Provinces. Now the field is clear for Mr. O. L. Bryce. Could you not persuade him, as an agricultural analytical chemist, to offer his valuable services to Sir Alfred Lyall who, in addition to sharing Mr. Bryce's views, would jump at such an offer, and take the first chance of supplying the Department of Agriculture with a long-felt want—viz., an *agricultural analytical chemist*? We should then be no longer shocked at having "experiments badly conducted," "notes negligently made," or the Department of Agriculture brought into discredit, and what is more to the point, those data of the highest importance would be carefully collated:

1. Dates on which seeds were sown.
2. Thermometrical and barometrical changes, direction of wind, &c.
3. Rainfall.
4. Analyses of soil, manure, and irrigation waters.
5. Quantity of straw per plant and bunch.

These essential points would be of course imparted to the outside world, and those who, like myself, are not *analytical agricultural chemists*, but merely amateurs, and as such, are so absurdly weak-minded as to call for impartial criticisms and—

FAIR PLAY.

P. S.—Mr. Bryce has tried to demolish Mr. Fuller: in fact, he has done so to his own satisfaction: but Mr. Bryce may perhaps recollect a tragic episode in the history of Constantinople. Heraclius Exarch of Africa demolished Phocas, the usurper, who had some time previously demolished Maurice, the Venerable Emperor of the East. Before Phocas was finally demolished, in the accents of despair being, we are told, in a very uncomfortable position (in fact by the orders of the avenger of Maurice, hung up by the heels for the inspection of an admiring multitude) he ejaculated: "Would thou have ruled better?" Mr. Fuller will, I know, excuse me for mentioning him in the same breath with the ruffian Phocas, but very probably after this demolition he may feel tempted to ask Mr. Bryce if he also "would have done better" had the Government of the N.-W. Provinces entrusted him with the charge of the Experimental Farm, Cawnpore.

F. P.

CASTOR SEEDS.

TO THE EDITOR.

SIR,—In your issue of November 1, "H. T. T.," writing from the Berars, mentions a large white variety of castor plant, which grows to a height of 15 or 20 feet, and lasts for several years. This variety is unknown to us down here, and I should be much obliged if "H. T. T." would kindly put me in the way of getting a small packet of seeds down to experiment with.

S.

Kurnool, Madras.

NOTE.—We have obtained and forwarded a packet of seeds to our correspondent.—ED., I. A.

CASTOR-PLANTING.

TO THE EDITOR.

SIR,—In your issue of the 1st November, "H. T. T.," writing from Berar under the heading of "Castor-Planting," mentions a "buckher." should be greatly obliged if you could obtain for me a description of the "buckher," with, if possible, a sketch. I have failed to get any one that I can trust to make up one, without a full explanation of it; and shall feel very grateful to "H. T. T." if he will help me.

J. O. T.

Bilaspore, December 8, 1882.

AN INDIAN TEA PLANTER ON THE TEA ENTERPRISE IN CEYLON.

(To the Editor of the Ceylon Observer.)

DEAR SIR,—I promised to write to you now and again on tea in Ceylon, and ought to have done so before now, but I thought it would be better to wait until I knew more of the climate and land I was writing about, so that I should not lead any one astray. I can now write to you on the subject with more confidence, having spent a year among you, during which time I have seen tea growing from 70ft. above sea-level to over 6,000ft., and I am well satisfied with the growth at all elevations, and I no longer doubt that Ceylon will yet be a great tea-growing country, and the sooner all who are interested in tea put their shoulders to the wheel to send to market teas that will sell at a profit, the better. This can only be done by giving careful attention to the plucking and manufacture.

Ceylon teas are now begun to be known in the market, and we should give our careful attention to the manufacture, so that our teas will get better known. We have all a great deal to learn about the growth and manufacture of tea, and none of us should be too proud to be taught. We can all learn from each other, and should be all willing to assist each other, as all are striving for the same end—that is, to make tea a profitable investment. This can be done; and why make a secret of the fact?

Now that our old love, coffee, has forsaken us, and that tea can be grown in the old fields among the coffee, why not plant tea among the coffee, but leave our old love to shelter tea, and should our old love give us a good crop, cut down the tea within six inches of the ground, which will only improve the new love, and make her flush and blush better than ever?

I am glad to see that Ceylon teas are improving, and I hope that they will continue to improve, although up to the present time there is some awful rubbish shipped from Ceylon, from some of the greatest tea growers in the island—men that should ere this know what good tea is and how it ought to be made, but still they will continue to ship rubbish to the market: in some cases they are ashamed to put the plantation mark on the chests. If they send tea at all to market, they surely should put the plantation marks on the chests, and, if any of us don't know how to make good tea, why should we not acknowledge the fact, and be taught by some one that may know more than we do ourselves on the subject? We can never be too old to learn. I would advise all the Ceylon tea-planters to exchange samples with each other and to visit each other; in fact, I would advise tea proprietors to give their superintendents 15 days' leave each year to go round and visit other estates. If they should see nothing to copy, they may see a lot to avoid; the mere fact of exchanging ideas with each other does a lot of good.

I have no longer any doubt about the profitable growth of tea in Ceylon, and I am sure that it can be profitably grown from 20 feet above sea-level to 7,000 feet. The flavour of the high-grown tea will make up for the shorter yield that one would get at a high elevation.

I consider with careful management that tea could be worked up to 400lb. per acre in the highest elevation in Ceylon, and in some districts in the low country I would not be at all surprised to see an average of 700lb. per acre reached, and what I mean is not 400 and 700lb. of rubbish, but of good tea that should average 1s. 5d. per lb. I could mention several estates that will turn out more in three months this year than they made in twelve last year, and all among that so-called poor soil of Avisawella and Ruawella, the richest tea soil in the island which will yet be the great tea districts of Ceylon.

I am glad to say a lot of land is now taken up for tea in the low country, which will increase the value of the oldest pioneers of the district's estates, who well deserve to be rewarded for going into a district that was thought to be feverish and deadly. Had the men that I am now thinking about gone in for tea in the way they went in for coffee, how different would their banking account have been to-day.

I understand that some enterprising proprietors are not going to content themselves with growing tea and cocoa only, but they are going to start a daily steamer, which will do a lot to open out the districts, and ought to pay the shareholders well.

Wishing good luck to the Kelaniganga Steam Navigation Company—

CHA.

AGRICULTURE IN INDIA.

(To the Editor of the Times of India.)

SIR,—I have read with interest the account, written by the Official Director of the Department of Agriculture and Commerce, N.-W. P. and Oudh, of the various experiments which he has made. There are some of which he records the results, that might have been taken for granted, from the general applicability of the old maxim that the more you work land the better you make it. His report seems as if he meant synthetically to construct agriculture in India, instead of applying the common principles that guide the best agriculturists in England, and from them eliminating the inapplicable details for such a climate and country as India. His report, in the equivocal language of the certificates granted by my respected professor of Greek, does great credit to his talents and industry, vouching for neither the one nor the other. Winter ploughing at home is considered much more valuable than spring ploughing, and winter manuring the best. Chemically speaking, the soil and manure get oxidised and disintegrated, and therefore more ready to take part in those chemical operations which result in the growth of plants. This is the result of his experiment when he has invested the soil two months prior to sowing. I notice his inversion is limited to six inches: his is a safe depth, but let him beware of following up his advantage too eagerly. Many a farmer has been ruined by falling in love with deep ploughing; he has raised his subsoil to the surface of the soil, and put himself in the position of the reclaimer of waste land, all the while he was paying rental for the best arable. Another old and time-honoured maxim is, "Don't work your land (while) wet." When you do so, you can easily understand that you are more likely to produce bricks than pulverised soil, and the return will correspond to the crops that could be expected off these varieties of soil.

The one great element that is wanting in Indian soils, and which is not supplied to them by manure as applied by natives, is nitrogen. Odours are to some degree nutrient, and in India where everything smells but the flowers, the deficient nitrogen of this soil may be supplied by the atmosphere. But here we have another example of misrule by the English in India: they are actually by sanitary measures impoverishing the air, and have not been able to induce the population to correspondingly enrich the soil. It strikes me that the Officiating Director, &c., is not proceeding in the way most calculated to impress them with the benefits of nitrification. The 77 per cent of nitrogen free in the air is inert and quite unfitted for purposes of vegetation; only when the nitrogen is in a nascent state, is it in the chemical condition, which permits of its combining with other elements. I will explain it crudely thus. For all practical purposes ammonia (N H_3) the ultimate resultant of manures solid or liquid, is the condition which we wish to reduce these to, so that by its decomposition nutritive material may be provided for plants. Chemically the operation proceeds thus, camel's dung, when treated yields sal-ammoniac; ($\text{N H}_3, 4 \text{ Cl}$), and when to this you add quicklime, you produce ammonia water and calcium chloride, thus $\text{Ca O} + 2 \text{ N H}_3 + 4 \text{ Cl} = \text{Ca Cl}_2 + 2 \text{ N H}_3 + \text{H}_2 \text{O}$, and what can be done quickly by means of heat in the laboratory, can be accomplished as effectually, though more slowly, by the sun's rays. To give another example: When you wish to make nitrate of potash, you expose animal's matter (containing nitrogen) in heaps, together with wood ashes (i.e. potash salts), and lime to the action of air: the organic matter gradually undergoes oxidation, nitric acid being formed, which first unites with the lime and then with the potash, to form nitrate of potash. What will be noted in all these chemical processes is that lime is 'quick,' 'living,' or in chemical sense nascent and ready for combination, and by its chemical power it acts as the key to open all the stores of nitrogen which may be presented to it. The Officiating Director, &c., has evidently heard that lime is a good thing, and that gypsum is the sulphate of lime, and that therefore it must be a good thing. But gypsum is a stable compound, and as inert for chemical combining purposes as clay or stone. He himself shows that it increases his outturn most markedly. Gypsum when moderately heated loses its water, and becomes that well known substance, plaster of Paris, which we all know becomes, on again being moistened, a hard cast. If he goes on with this, the Officiating Director, &c., may eventually be able to supply the British public with a very correct plaster cast of an Indian landscape, and the authorities at the Zoo might be induced to lend the tigers to make it life-like.—Yours, &c.,

Berar, November

T. HUME.

BEE CULTURE.

(To the Editor of the Madras Mail.)

SIR,—With reference to the article on "Bee Culture" in India in your issue of the 27th instant, allow me to state that for years I have been interested in the subject, and several times succeeded in partly domesticating them for months; but the difficulties I had to contend with were great. It is so difficult to get the natives to attend to instructions without constant supervision, and from various causes I was unable at the time to give the subject my personal attention, and they resulted in eventual failure. There are three kinds of bees common to these hills. One of them is identical with the European species, the *Apis mellifica*. To clear up doubts, some two or three years ago I sent specimens to F. Moore, Esq., of the South Kensington Museum, and that gentleman was good enough to identify them as the *Apis mellifica*.

Not long ago a notice was in your paper calling attention to the subject, and stating that some savants in Germany had written to the German Consul at Madras for information about bees, and more especially about the *Apis dorsata*. Within a day or two after seeing this notice, I collected specimens of the three kinds of bees found here, and sent them to the Imperial German Consul, Albert Gerdes, Esq., at Madras, with the request that he would kindly submit these specimens to his friends in Germany for identification, and should they care to have any of them, I should be happy to collect and send them, on condition that they send out two cages, and that I would fill one, and send it to it to them, and the other cage I purpose keeping for myself, with a view to carry on further experiments here; and should his friends wish to know anything of me, I referred them to Dr. Jagor, of Blumeshoff, Berlin; but I regret to say that Mr. Consul Gerdes has not had the courtesy to acknowledge the receipt of my letter, or the specimens as yet! I may further state I have been in treaty with Messrs. Neighbour and Co., through my son-in-law in England, to get out a beehive, with a swarm of bees, and that they had arranged to send me out their "Kilburn Collateral Frame Hive," but unfortunately some friends who were coming out, and who were to have taken charge of the hive, had to postpone their departure indefinitely on account of ill-health. Thus the opportunity was lost of sending out the hive. Advice received the mail before last states that Neighbour and Co. were arranging with the agents of the British I. S. N. Company to send it out by one of their steamers, and I hope to receive it before long. Honey is plentiful during the season up here; the collection is contracted for by the Mullialles, and sold at 5 annas a quart bottle, but at times we have to pay eight annas the bottle. The honey thus brought round for sale is generally very pure; it is liquid, viscid but translucent, and it has a very sweet taste. If kept for a time the honey becomes thick, white, and granular in texture.

JOHN SHORTT.

The Indian Agriculturist.

CALCUTTA, JANUARY 1, 1883.

CAWNPORE FARM EXPERIMENTS, 1881-82.

No. I.

THE Cawnpore Farm experiments for 1881-82 are officially held to establish that "the main problem of practical agriculture in India is to supply nitrogen in the form of a cheap manure." It is nitrogen alone that is deficient in Indian soil. To this declaration is added another (*vide N.-W.P. Government Gazette*, 9th September 1882) that "the great increase in produce which results from early ploughing is almost certainly due to the amount of nitrogen in the form of ammonia, which it enables the loosened soil to absorb from the rain, and, probably, from the air as well." The first is an original—a very original—postulate as respects India; the second is—well, the unconscious reproduction of a familiar axiom laid down by Liebig some 30 years ago, and endorsed by all agricultural authorities. But possibly none of these are represented in the Cawnpore Farm library, and the fact in question has doubtless been evolved from the depths of the inner official consciousness. It is satisfactory, however, to have this additional testimony—although needless—to the worth of a long established

deduction in favour of the atmosphere and rain being the sources of nitrogen.

The Cawnpore Farm experiments are in their infancy, and must pass through the initial stages to adulthood with the usual ordeals of measles, coughs, and convulsions. About forty or more years ago there was a craze among European farmers about *nitrogenous manures*. It died away when their true value was known: it will disappear at Cawnpore under similar enlightenment. Comparative experiments have everywhere proved that the use of any one fertiliser, whether nitrogen in any of its forms, or lime, potash, phosphoric acid, or others, has always produced conflicting results, indicating, as a disturbing cause, the presence, in different proportions in the fields experimented upon of some available plant-constituent or constituents which the fertiliser assisted the plants in absorbing. It follows that the repeated use of a given fertiliser (as proposed for nitrogen by the Assistant Director of Agriculture) must progressively impoverish the soil of the co-active constituents sooner or later, and reduce the outturn of the crops to nothing. Mr. Fuller's experiments have not embraced this feature of the case, or he would not have overrated nitrogen, essential though it is to plant economy. That *no one plant-constituent is of any value in the soil by itself*, and that several contribute to make up a plant, is a cardinal axiom that should never be lost sight of. The Cawnpore experiments conclusively establish this. An *unmanured* soil (page 288 of the *Government Gazette*, already quoted) yielded 771 lb. of wheat per acre. The same soil, fertilised with nitrate of potash at 240 lb. to the acre, yielded 1,605 lb. Difference in produce—834 lb. Another *unmanured* soil yielded 777 lb. per acre, and when similarly nitrated, produced 1,242 lb., difference in yield 465 lb. If nitrogen is all that Indian soils need, explanation of the disparity in yield of the nitrated plots is necessary. The two *unmanured* soils, it is worthy of note, were in the present instance in identical conditions for experiment. There was a difference of *only 6 lbs. per acre* in their *unmanured* yield; yet, when nitrated, one field yielded 369 lb. per acre more than the other! There is but one explanation of this. One field had more assimilable plant-constituents awaiting excitation with activity by nitrogen than the other; and the conclusion that follows is, that *something besides nitrogen* is needed for Indian soil.

The above illustrates also the wide variations in latent fertility over small areas. The rule holds good everywhere. It is quite to the point to suggest that the above noted difference in yield of 369 lb. per acre, or, for the benefit of those accustomed, to think in Government bigahs, 6½ maunds per bigah is not a maximum difference. The possibilities of experiment might at any time furnish two fields that, in an unmanured condition, would yield a difference, say, of 100 lb. per acre; but fertilised, whether by nitrate of potash or phosphates or other constituent, the apparently inferior field might yield 1,000 lb. per acre more than the other. The explanation in this case would be just the same as in the Cawnpore experiments. The fertiliser would be assisted through more co-active plant-constituents being present in one field. Our present agricultural knowledge does not extend so far as to determine what combinations take place within the soil, and we cannot tell what the effect will be by the addition of fertilisers, or by combinations of them. We can tell generally only after a crop is raised what the effect has been, but we cannot predict from this the effect on fields elsewhere; so that, whatever the results with certain fertilisers on certain fields may be, they hold good only for those fields, and only for the occasion in question. In the Cawnpore experiments nitrate of potash was found good for two fields there. The results were true for them only, and for that occasion. Nitrate of potash might have yielded superior or inferior results elsewhere, or even in the two self-same fields on repetition of experiments. What holds good of the nitrate of potash in these cases, is equally true of other fertilisers, or combinations of them. The question then is: in the absence of any knowledge of combinations within the soil, what conceivable purpose is served by experiments, such as those in the Cawnpore Farm, and, for years, elsewhere? Probably, experimenters hope to fluke into some discovery that

will prove the key with which the untold agricultural wealth under our feet is to be unlocked.

No one article could be universally used as a fertiliser. The supply could never meet a fraction of the demand. Two hundred and forty pounds of nitrate per acre were used in the Cawnpore experiments. Every 1,000 acres would, therefore, need 240,000 lb. of nitrate annually! From this simple illustration may be judged the feasibility of supplying, even under the proposed freedom of saltpetre manufacture, the requirements of a single district in the North-West Provinces and Oudh. We may, in fact, dismiss the notion. The country is virtually no better for the alleged discovery of the efficacy of nitrate of potash as a fertiliser. Millions of acres must remain without it. What the effect might be of annually saturating the soil with saltpetre is a point that requires careful consideration on behalf of the very agriculturists whose interests are sought to be promoted.

But discussing the Cawnpore experiments on other grounds, a radical defect in the conditions vitiates the results. The area of each plot—*viz.*, one-twelfth acre—was too limited for reliable results. The most conservative settlement officer, afflicted with a craze about State rights, would not attempt the computation of the out-turn per acre over a large area from so small a plot as one-twelfth of an acre. He would never base the Government demand on the produce of one-twelfth of an acre of the most fertile field in a village in order to "vindicate Indian agriculture." An insignificant twelfth of an acre, carefully fertilised and sown with picked seed to the utmost fraction of a square inch, solicitously tended, and irrigated opportunely *no less than four times* during the growth of the crops! Are these the possible conditions of Indian agriculture, whether by wells or canals? If this is the way the Department of Agriculture intends to develop the potentialities of the soil, it will have to wait for a teeming population, minute sub-division of land, a saltpetre factory in every village, and an inexhaustible water-supply.

II.

THE poverty of a given soil is simply a question of degree.

It might be rich enough for the production of an abundant crop of some sort, yet poor in comparison with other soils. This is the position of the Cawnpore soil, which the farm authorities declare is "generally poor and nowhere of exceptional fertility." Yet on an "unmanured plot which had been watered only twice, the crop (wheat) reached the very high outturn of over 44 bushels per acre!"—(*N.-W. P. Gazette*, September 9, page 284,—very little justification for denouncing such a soil. But the outturn in the given instances and others less remarkable is attributed to the use "of a soil-inverting plough." While admitting the advantages of such a plough under the supplementing conditions of a needful supply of fertilising matter, it is a reasonable assumption that the Cawnpore farm has, during various experiments and operations over past years, received manures of sorts directly and indirectly to an extent which is impossible to ordinary Indian agriculture. As no crop exhausts the manure specially supplied for it, some is still left in the soil. It is carried down or diffused beyond the reach of the roots. This aspect of the question has been often discussed, and it is estimated that from about one-third to a half only of such manure is removed by a crop. The spaces between the roots of one plant and those of the surrounding plants represent untouched fertility, and the aggregate of such spaces is from one-half to two-thirds of the total area covered by a crop, according to character. Part or all of the remaining manure is doubtless removed by subsequent crops; but considering that every portion of manure is not immediately assimilable, a residue of fertilisers is always more or less present in the soil of experimental farms. Again, some crops will remove more constituents of one sort than others. Unless, therefore, the history of every field or plot in an experimental farm is carefully and accurately kept, it will be difficult to estimate the value of experiments, with specific manures, or with unmanured plots, *i.e.*, plots not manured for experiments. It will have been seen from the previous article that of two plots

in unmanured fields in the Cawnpore farm, one yielded 771lbs. and the other 777lbs. of wheat per acre. For all practical purposes the difference of 6lbs. per acre is nothing. Yet in these self same identically-conditioned fields, two plots, manured each with 240lbs. of nitrate of potash, one yielded 1,342lbs. of wheat and the other 1,605lbs., or a difference of 263lbs. per acre. There must consequently have been a marked difference in the amount and character of the residue of previous manures in the fields in question, and of the assimilable constituents of the soils themselves (by different rotation of crops) which the nitrate of potash started into activity. As argued before, it is not one constituent, but a combination of constituents, that go to make up a crop (an old established fact), and therefore any results obtained by the use of nitrate of potash alone would not demonstrate the exceptional value of the nitrate, nor justify the deduction that "the main problem of practical agriculture in this country is how to apply nitrogen in the form of a cheap manure."

The matter is susceptible of further illustration. The total amount of nitrogen removable by a wheat crop of 20 maunds or 1,600lbs. per acre is given (at pages 290 and 292 of the *Government Gazette* aforesaid) at 45lbs. per acre. The amount of nitrogen in 240lbs. of potash is quoted (at page 289) at 12 per cent or 29lbs. But these 240lbs. of nitrate per acre could not all possibly have been directed to the roots of the plants. Diffusion over and within the soil rendered available about half. 14½lbs. of nitrogen then were utilized by each crop. But the field producing 1,242lbs. of wheat or 15½ maunds per acre, removed 35lbs. of nitrogen, and that yielding 1,605lbs. or 20 maunds per acre removed 45lbs. Whence did the excess of 20½lbs. of nitrogen in one case, and 30½lbs. in the other, come? Even if we suppose the whole 29lbs. of nitrogen to have been assimilated by the crops—an impossibility—we still have an excess of 6lbs. in one case and 16lbs. in the other to account for. Of course it was furnished by the soil and the air. But why an excess of 6lbs. in the one case and 16lbs. in the other, unless we turn for an explanation to the different latent conditions of the two soils, induced by the unequal residues of previous crops and manures, and by the different states in which dissimilar rotation of crops left the soils to be acted upon by the nitrate of potash.

No reason is given in the farm report for preferentially employing the nitrate in the experiments in question. In fact, these experiments are but counterparts of all others at Cawnpore and elsewhere. Given a manure or fertilising agent, to discover its value is the problem unintelligently sought to be worked out, but which will certainly never be, beyond the point that a fertiliser must comprehend one or more soil-constituents, or, which is the same thing, one or more plant-constituents. And this can be done without resort to expensive and valueless experiment—namely, by comparative analyses of fertiliser, crop, and soil. To show how little the soil at Cawnpore needed nitrate of potash, analysis at Roorkee (page 290 of *Gazette* aforesaid), showed that it possessed to a depth of 9 inches 5,717lbs. of nitric acid, equal to 1,483 lbs. of nitrogen per acre; and potash 16,335lbs. per acre. Nevertheless with this foreknowledge of the wealth in the soil, 240lbs. of nitrate of potash containing 29lbs. of nitrogen were added to the soil. Why was this done when nitrogen enough for 33 crops of 20 maunds each, and potash enough for 600 such crops, was present within a depth of nine inches in the soil? No explanation of the proceeding is to be found in the official report in question, any more than in other like recorded cases for years previous anywhere, whatever the fertiliser used, whether simple or compounded. Justification to a certain extent can, however, be found on some such basis as the following. The Cawnpore soil was analysed to a depth of nine inches. Fertility diminishes downwards, the ratio has not been as yet even approximately determined and systematised under soil classification. The maximum fertility of any soil is, however, known to be within the depth of the first three inches. The inversion of the soil by ploughing reduces this upper fertility proportionately to the depth and uniformity of inversion. To get, as far as practicable, the average fertility to the depth of inversion, it is advisable to take portions of soil to such depth, say for every

three inches of the section, and after mixing thoroughly to analyse the same. This was done at Cawnpore. The result obtained—namely, 1,483lbs. of nitrogen, and 16,335lbs. of potash per acre—requires to be reduced by two-thirds or by half, according to the root-space occupied in surface and depth by a crop, as before shown. This will give 497½lbs. nitrogen and 5,445lbs. of potash in one case, and 741½lbs. nitrogen and 8,117½lbs. of potash in the other—within reach of the roots of the crop. In other words, in one case 11 times as much nitrogen and 200 times as much potash as would be required by a crop of 20 maunds of wheat per acre; in the other 16 times as much nitrogen and 300 times as much potash for the same crop. Therefore, justification still fails for the empirical addition of 240lbs. of nitrate of potash containing 29lbs. of nitrogen. None was needed, if any dependence on analysis is to be placed. The fact is that in all experiments the well established fact of years is overlooked—that the fertility of a soil is represented by the assimilable plant-food it offers. No rule for determining this has as yet been found, and no effort is made in the direction either. That by adding fertilisers the soil is made more than naturally fruitful has been known for ages in agricultural history. But how much a given soil requires for a given crop and what the constitution of the fertilizer, we are nearly as ignorant of now as in days of yore. That the assimilable constituents of a soil will vary in quantity and character after a crop and with the crop to be raised, is manifest no less than that the quantity of a fertiliser and the proportion and character of its constituents should vary with crop too. The determination of these points is essential, as also the constituents of a fertiliser that (1) are assimilable within the time needed to benefit a crop, (2) that acting on, or acted on by others in, the soil will augment the assimilable constituents needed. It will then become possible to estimate the composition and quantity of a fertiliser in harmony with (1) a given crop (2) to the ascertained physical condition of the soil reserved for that crop.

Herein lies the future of agriculture. He who resolves these points will unlock the long-hidden potentialities of the soil.

A. P. W.

THE GOVERNMENT OF BENGAL AS A LANDLORD.

BEFORE many days have passed, Mr. Reynolds will introduce the Rent Bill into the Legislative Council of India. The time is most opportune to remind the Lieutenant-Governor that he is himself, on the part of Government, as great a landowner as any private individual in these provinces, even such sacred magnates as the Raja of Burdwan and the Raja of Durbhanga; and to enquire how his predecessors have fulfilled this great trust which affects property of the value of twenty lakhs a year. We know that in England the Government does not require reports on the conduct of landowners, does not lecture or reprove them, and has scarcely interfered with them by legislature; but on its own estates it has shewn an example of moderation as to rents and generosity in improvements. All Crown lands are let on easy terms, and much enterprise has been shewn in draining, fencing, and providing suitable farm buildings. In India the Government has been much more free in its censure upon others, more ready to interfere with the strong hand of the law; so it might be supposed that its own conduct would be even still more above reproach. We might expect to find that in every district the Government estates formed a model of good management, with rents moderately assessed, the best means taken for the security of the tenant, and a provision for improvements so liberal that a marked difference might be observed between Government villages and the surrounding tracts. Such would be the reasonable expectation from the experience of England, and from the language addressed by officials to private owners: what are the facts?

Moderation in the exaction of rent is the first principle of good management, most of the ordinary evils of agriculture merely because they lead to the oppression of the tenant by rack-renting. Has Government estates been any more liberal respect to private owners? We see from the reports that no very recondite authority, that officials having rent rates are not expected to set an example, but to follow one,

taking the rent rate of private lands in the neighbourhood for a guide in assessment. Provision is made for cases where the private rents may appear too low, and then some other reason is to be sought for enhancement; but nothing is said as to rejecting the standard where the private rents are too high. It follows that, under the rules, Government rent must always be as high as that of private land, and often higher. We notice that, taking the average of all the settlements made last year, the enhancements were about forty per cent. of the original rental. Government settlements are for short periods, say ten years, and if forty per cent. is added at each renewal of the lease the rate will double every twenty-five years, and by mathematical progression increase sixteen-fold in the century. This, it will be admitted, is quick work; the pace is rather rapid for the ordinary ryot of Bengal. To take another test, that of the satisfaction of the tenants. We find that they are very generally combining on Government estates to resist enhancement, and even to make a demonstration, by refusing all rents. Many of the Government ryots of Midnapore have been seen in Calcutta assembled in large bodies to protest against enhancements, which it is admitted were excessive, and in some instances absurd. In Noakhally, the Civil Courts have declared some of the enhancements made by Government positively illegal. These may be isolated cases, but what are we to say to the fact that last year only three-fifths of the current demand was collected on the whole of the Government lands? If short collections in a good year are a symptom of rack-renting, its presence in an alarming form cannot be denied. It is seldom possible to know what proportion the rent bears to the value of the crop, but we have this information as to the largest Government estate recently settled, that of Khoordah, near the Tributary Mohals of Orissa, which it resembles very closely in character. The proportion there is one-fourth. Now one-fourth is the highest proportion which, under the new Bill, can be taken from ryots on the richest lands, near the most populous towns, where competition is closest. How this maximum can be exacted from a primitive people cultivating a half-reclaimed jungle in an inaccessible region, is a puzzle for Mr. Reynolds to explain in his double capacity as member of the Board of Revenue which confirmed the settlement, and the introducer of the Bill in the Indian Council.

As to the protection of tenants at the rents imposed, it is to be noted that the system most inimical to it is that of introducing middlemen, who farm, not the land, but the ryots, taking them over in a body to make money out of them. This is called the *ticcadari* system, and under that name, has been denounced by all officials unanimously. It introduces, they say, men with no interest in the estate, except to screw the last penny out of the tenants during the short period of the *ticcadar's* lease, men who have made a trade of the art of doing this, and who do not scruple to adopt means such as ruining a recalcitrant ryot by forgery and false charges. Such being the Government view of the *ticcadari* system, we must ask why the system is extensively adopted on Government estates? We suppose that more than half the Government estates are thus farmed out. The rule is to manage such estates directly, where it is not inconvenient to do so, and it is so often inconvenient that the middleman is quite a Government institution.

The great reproach against the Bengal landlord is that he does not improve, or even maintain, the farms on his estates. An English landowner builds the farm-houses, digs the drains, plants the trees and hedges, makes the gates, and hands over the land to the farmer ready for the plough. It is objected to the Bengal zemindar that he does none of these things; that he sits by while the land is converted from primeval jungle into arable fields, sees the occupier raise the farm-houses, cut the undergrowth, break the soil, and dig the wells, and then demands nearly the whole profit. It has even been urged that, being a mere unproductive burden on the land, he may properly be put aside. Now, this description, it must be admitted, applies to Government, as a landlord, without any qualification whatever. Private owners claim to have improved in some places; it can be proved that Government, as owner, never improved. The railways, roads, and canals made have no special reference to Crown lands, and are executed by Government as ruler of the whole country, not as landlord of certain definite estates. The only provision made for the improvement of

these was a fund of five per cent. on the rental. In many districts this has never been drawn, and where touched, it was devoted to education and roads, and not, except in some infinitesimal degree, to improving the estates. The fund has been abolished, and in its place there is to be an allowance of seven and-a-half per cent. on rental, for collection expenses and improvements, the allowance to private persons, for collection only, being ten per cent., and often twenty. It is plain that little or nothing for improvements can come from such a fund. On the majority of Government estates, the landlord contributes nothing, directly or indirectly, to make or maintain or improve, and is as much a mere drag on agriculture as the worst private owner can be.

It will certainly be an awkward position for Mr. Reynolds when he has to appear in the legislature as the champion of the last of tenant-right, reduction of rent, compensation for improvements, and so forth, he being, as the member of the Board of Revenue, in immediate charge of Government estates, the representative of a system of management of which the three catch-words might be, "high rents, middlemen where convenient, and no improvement." He will remind many, of the crab in the fable cautioning its son against walking sideways; of the tipsey preacher at the temperance meeting in *Pickwick*, who accused his audience of being drunk; of the warning of Ophelia to her brother—

Do not, as some ungracious pastors do,
Show me the steep and thorny way to heaven,
Whilst, like a puff'd and reckless libertine,
Himself the primrose path of dalliance treads,
And recks not his own rede.

But we hope that he may really be rather like the father in the story-book, who learned morality and religion in teaching them to his son. The position in which the Bengal Government has now placed itself, as the defender of the ryot in the legislature against rack-renting, must, we hope, force it to play the good landlord itself. Already, in many ways, we see signs of the doubts that precede repentance and amendment. Sir Ashley Eden would probably have denied that there was much amiss on Government estates, but Mr. Rivers Thompson seems to admit that there is, and to be preparing for reform.

PETROLEUM IN ASSAM.

WE read in a London trade journal that—"Advices just to hand from New York inform us that the production of petroleum at present is at a figure but little greater than the demand for it. The rapid decline in the yield of the producing districts is causing unusual apprehension in the minds of those in the States who look farther into the interests of the petroleum trade than the speculative branch of it affords." It would seem from this that the enormous demand made upon the oil deposits for the last quarter of a century are at length beginning to tell, and that the American springs, vast as they have hitherto proved themselves, are by no means inexhaustible; no doubt, were extraction to cease for a time, and thus permit natural distillation to replenish the springs, the supply would become as bountiful as heretofore, but chemical knowledge has not, as yet, enlightened us as to how long the process of distillation requires; and petroleum, like coal and other indigenous deposits, has been regarded in the light of a widow's cruise, fully equal to any demand made, or likely to be made, on it. In the face of the possible falling off in the yield we note that "sales have been enormous, and a considerable rise in price is anticipated." Looking to the numerous uses to which petroleum and its derivatives are put to, and their probable extension, it is time, we think, that the mercantile community should bestir themselves, in view of opening up and developing the springs known to exist all over and beyond the north-east districts of Burmah and Arakan. It is true that the Assam deposit remains practically locked up from the paucity of local labour and inadequate means of carriage, but it is reasonable to suppose that the river steam companies would meet enterprises half-way, and lower their freight so as to admit of the mineral being placed at the site of export with some margin for profit. The rates ruling in London, when the mail left, were 7d. per gallon for common to 7½d. and 8d. for refined, with the prospect of an immediate advance; and though it lies not within our

province to express an opinion as to whether such prices would prove remunerative, we give the information for the benefit of those who might consider the matter of prospecting during the ensuing cold weather. In the event of the supply ceasing, or falling off to an appreciable extent, from America, British India is practically the nearest source of supply, and the comparative slight depths of the springs in the vicinity of our surface coal deposits, coupled with cheap labour, should give the Indian mineral decided advantages. It is not very creditable, we take it, that we should go on importing a daily requisite, when its presence in abundant quantities lies within our own borders. To those who may be under the impression that the assertion of the diminished supply is but a *canard* set afloat by an "ile ring" of speculators, we may mention that the State authorities have for some years past issued repeated warnings, at the instance of competent mineralogical experts, that the springs in America were being drawn upon in a manner incompatible with prudence. Even were the prospect of a profitable export trade not sufficiently clear to admit of large works being undertaken, there can be very little doubt that considerable gain would accrue to any enterprising individual who would undertake to tap the springs in Assam, refining on the spot, for the purpose of meeting the demand in the local markets. The universal avidity with which all classes have taken to the use of kerosine for light and cooking, and the consequent enormous consumption, affords reasonable justification for predicting success for the working of petroleum in a properly organised manner; and now that what was formerly termed "the waste," possesses, under the name of vasiline, profitable commercial value, we have additional inducements for the launching of a new and non-speculative enterprise.

THE WARRORA COLLIERY.

Br H. T. T.

A VISIT to the Warrora Colliery will well repay any moderate trouble and expense incurred in it. Situated centrally in the continent of India, and perhaps with design by the Great Disposer, where raw materials exist in lavish abundance, it is the natural fuel-supplier to a large extent of country, and would, under any other than its present and past management, have fully developed its unrivalled advantages of supply to the perfecting of existing industries and the promotion of many now unformed, and would have yielded returns which would have satisfied the most exacting. For had there been any prospect of a continuous supply of fuel, the iron, richer in its ores than in any other part of the world; the cotton which, for its manufacture, has to travel hundreds and even thousands of miles; the slate quarries, paper, wood, oil, sugar, and spirit material—would have each and all started for themselves local houses of manufacture. After 12 years of working, however, under the present direction, the colliery almost totally failed the other day, and the output of coal has been beyond computation meagre—indeed, so bad that the few cotton presses and two or three spinning mills, with this coal at their very door, and desirous of using it, have to burn dearer wood; and the G. I. P. Railway, its largest customer, is supplied spasmodically and scantily, so much so that it had to arrange till very lately for its local consumption 1,000 miles away, although this colliery is only 45 miles from its line. The great anomaly at Warrora is that very many trucks of wood—grand old tamarind, mohwa, and mango—leave the station daily for the mills in the Central Provinces and the Berar. The basin, collectively designated as the Warrora coal measures, is hardly as insignificant as you have been led to believe. It is in fact of wide extent. Known to extend to Chanda, 30 miles south—for over this tract small masonry pillars mark where borings have found coal; and miles to the south in the Nizam's territory on the line of the proposed Chanda and Hyderabad Railway, the seams discovered point to the presumption that the coal is continuous. Then, at Peacegaon in the Berar, 30 miles in a south-west direction from Warrora, shafts were sunk, machinery imported, and preparations were made by Government to work the coal on a grand scale, but, from some cause or other, the scheme was nipped in the bud, the machinery has become worthless from neglect, houses and stores are in ashes, as well as the prospects and outlay on the undertaking. Between Warrora and Peacegaon coal has been found at Wun and other places, and the river Wurdha flowing in a south-easterly direction, midway through this tract, towards Chanda, has coal cropping up at all places. So, leaving out the mineral found in the Nizam's territory, we have a certain area of at least 600 square miles in the Central Provinces and Berar, with three seams of an average thickness of 12 feet each, within a mean depth of 300 feet, the first two lying beneath

only clay and shale, and the third beyond this and a few feet of sandstone. It would have been almost impossible, one would have thought, to have misdirected an undertaking so favored by nature, and with little ingenuity this scheme, with a railway to the pit's mouth, abundance of labor, and untold funds at disposal, would have been projected to undoubted success; and it is difficult to compass the startling and almost incredible fact that, stares us into dismay, that the enterprise has hitherto resulted in failure. If ever the acts of man demanded a Royal Commission of enquiry, they do here. For from the extent of public funds involved and meagre results, there can be only one tale revealed—of incompetence, gross fraud, and waste. The administration of the Central Provinces by Mr. Morris has been by no means a success, and for the whirlpool of funds lost in this colliery speculation, he must be held primarily responsible. A ruler after the type of the great Sir Richard, he possesses all that statesman's autocracy and speculative propensities, without that energy which makes personal rule felt to advantage; without that discernment—the gift of even mediocre men—which instinctively spots the right genius and means to carry out the right undertaking; and without that malleability which adapts itself to the altering relations of the state with "interlopers" and their industries. He has, therefore, centred in himself all power, patronage, and authority, even to its widest details, possessing a mind whose every effort has been directed to the discouragement and stamping out of all private enterprise, by involving Government and dissipating its resources in coal, railway-aaleper supply, horse dawk, and even hotel speculations: all having one issue—miserable failure. His revenue administration, instead of having, with inducements, opened out a fertile country, has left in a state of virgin forest almost three parts of the province he rules, and the revenue of his government is nearly stationary, as in the days, many years ago, when he assumed office. The only returns which show a large increase are those derived from abkari and litigation, and organised crime is rampant in his dominions. His sanction and recommendation of the Chutteesagurh Railway on the narrow gauge, simply because the misguided power above him favored it, must ever leave on him the indelible stamp of incompetence, for he very well knew that it would immediately have to be pulled up, because a break of gauge could never be tolerated for a moment on the highway from Calcutta to Europe. Hence, notwithstanding our liberal Viceroy's praise and quoting of him as an advanced Liberal, he still remains a fossilised autocrat, true to the instincts and traditions of the Haileybury set, and his race, happily fast dying out, mark, by way of contrast, what rapid strides a neighbouring province, Berar, has made under Mr. Jones—able, hard-working, honest, and who strives to do his duty by all. The revenue, while Mr. Jones held sway for five years, trebled itself, and the province—a third of the Central Provinces—yields nearly as large a revenue. Waste places have been peopled and opened out with roads, private industries cherished, and the country, a hot-bed till lately of serious crime, quite purged of it. Men reared in the traditions of the Commission, with few exceptions, get so bound up in red tape and routine that, by the time they attain the period when they should govern a province, their ideas are so cramped from circling in limited spheres and appointed grooves, that they are altogether unfit to administer the destinies of a large territory in these days of rapid change and liberal thought. And there is no question but that these rulers should come to their posts free from the trammels of local prejudice and tradition; and the time cannot be far distant when able statesmen at home or in the colonies will be selected to fill posts even so low down in the scale as Chief Commissionerships in India. Most people then will agree with me, when I repeat that the head of this autocratic local administration is to blame for the failure at Warrora. For nothing would have been easier at any time than for him to have thrown off the shackles of departmental environment, and made over this (to the State) white elephant to a company, whose sole business would have been to see that it did pay, and not have lent himself, through a series of years, to the squandering of Government resources to the tune of nearly a crore of rupees without any appreciable return.

Warrora is situated in the Chanda district of the Central Provinces, 45 miles south of Wurdha, the junction of the colliery railway with that of the G. I. P. Sandstone quarries abound about here, and the line and the railway works look business-like, and substantial pillars of solid stone 8 feet to 10 feet in height, and copings to the bridge parapets, many tons in weight, of a pleasant, yellowish, grey color, speak of solidity in all the masonry works. The rail track is on the broad gauge, and the colliery is a mile and a-half from the Warrora station. There are two pits in working, Nos. 3 and 4, and one shaft, No. 5, is in course of being sunk; but owing to insufficiency of pumping power at the site, the work has been suspended. Mr. Foster recommended that, instead of an outlay in machinery, a gallery should be driven to it through the coal from the third seam of pit No. 2, past No. 1 pumping station, and so drain the water, and this has saved the Government a good deal of money. There are two pumping stations, and a third is being formed for the new Attock engine. This was brought down from the Punjab, and for its cost and carriage and buildings, there is an estimate of three lakhs. There is too much pumping

power concentrated in a small space; and the Attock engine will soon have to be removed at fresh cost to a place much further south, which way the coal dips. The coal pits form a triangle a quarter of a mile apart, and the works are on a slightly rising hill. There is one substantial masonry building for the Attock engine nearly ready, a few walls for Nos. 1 and 2, and brick and stone and mortar do not much predominate elsewhere. Iron roofing and sheeting are chiefly employed for the pit and engine sheds, and solely in the workshops. You have already sketched the earlier days of this enterprise, so I need not be largely retrospective. On the principle that a district officer is expected to be Jack of all trades—Judge and revenue officer, agriculturist, accoucheur, and stone-mason, so each official in the D. P. W. is expected to be master of all branches of engineering. Hence are they, because their learning and experience extend to road-making and bridge-work, deemed capable of directing colliery, architectural, and marine undertakings. And this faith in their universal ability, and the want of discretion in choosing the proper management, had all to do with the failure at Warrora. When private concerns require skilled direction, they follow the only proper method to obtain it—Advertise. But if such a course were followed by the D.P.W., it would only call in question its individual and collective God-given attributes, and this could not be thought of for a moment. Before proceeding, it would be best to notice that the charges for prospecting, boring, and testing the coal amount to something like 10 to 15 lakhs!! In the D. P. W., lakhs are spoken of just as you and I would talk of hundreds. Mr. Ness, a mining engineer, with little experience of machinery, was appointed to the charge of the mines in 1873. The engine-power was not sufficient to do the work exacted of it, so little progress was made, and this with extreme difficulty, delay, and expense. The head of water had been greatly under-calculated, and new sets of pumps, larger and larger by degrees, were continually indented for and new engines and boilers were also from time to time brought out. The happy mean of what the work actually required was never hit on the head till lately. Constant breaks-down, flooding of pits, and the work commenced *de novo*, as if nothing had been accomplished during a long period; no honesty at all in the subordinate staff; excessive charges for labor and material ran up in the course of years to a fabulous sum. Coal of course was being extracted, but never steadily. Men who could advise were never consulted, but any experimental machinery recommended by any one in the department, and principally by the Chief Engineer, Mr. Armstrong (of road and building experience), was at once adopted.

Such is the doleful tale of the industry for eight long years, when an order came in 1879 from the G. I. P. Railway for 3,000 tons of coal a month. The manager, weighed down perhaps a little by a retrospect of the sad vista of years of failure, now began to hope that brighter days were in store if this order could only be fulfilled. Machinery that was manifestly unequal to the task both of mining such a large amount of coal and keeping the pits dry, was put to great strains to meet the demand on it, and as both achievements were beyond its power, the most profitable drawing coal was put full on. When the water made headway, it was sought to both wind and pump to the full, with the natural result—utter breakdown of machinery, consequent flooding of pits, and all work at a dead stand, to be done over again; and the stoppage continued for nine long months. It was now decided to change the local management, and a Cooper's Hill man, Mr. Reynolds, from the Ajmere Locomotive department, whose only *forte* was mechanical engineering, without even a knowledge of the rudiments of practical mining, was appointed in the stead of Mr. Ness. The machinery was now renovated, replaced, and fitted up to purpose, and the work got under weigh just as if it was a novel undertaking. But from the absence of mining knowledge, the work in the pits began to suffer, specially retarded by deficient air circulation, the assistant in charge of the underground section being no practical miner. Matters pulled along at haphazard, the yields at times being very large and at others the reverse, when in January 1882, fire was discovered in pit No. 2, a couple of hundred yards from the bottom of the shaft in a north-east direction, originating, it was discovered, in the pyrites and excess of sulphur in the root coal. Then the fire, which it was thought had been silenced, broke out again and again, having travelled by the roof. During months, while the seam was on fire and the process of stopping and isolation continued, the work of quarrying was proceeded with, though daily many of those working at the stoppages, masons and *beldars*, were carried away insensible. This dangerous work continued till July, the fires assuming more and more formidable proportions, and threatening disaster. On the 23rd, a rather larger escape of noxious gases had laid many people low, and the Assistant Mining Manager, Mr. McDonald, being informed, he proceeded down the main pit No. 2, while ordering one of the underlookers, Hartland, to go down pit No. 4, and meet him half-way. The foul air was plentiful, having been let in through a breach in the "long wall," and about 80 men lay in a state of coma, who, if not taken away and revived at once, would certainly die. Mr. McDonald came on the scene for a moment, asked the underlookers, Turner and Hartland, if he could depend on them for carrying people away, and on their replying in

the affirmative, retraced his steps, saying that he was "feeling very bad." He had not gone ten paces, poor fellow, when he fell in the gloom never to rise again. The underlookers, Turner and Hartland, worked very hard, saving many lives, till there were only left the latter, a native man, and a peon boy to take away a dead man. The underlookers had twice fallen down, and been brought to. The little peon boy now began to show signs of succumbing, and was being helped along by the native; while Hartland staggered beneath the dead weight he was carrying. The boy, Jamia by name, seeing this, told the man, while the dreamy languor was fast overpowering him, "Never mind me; let me lie; take along the *soob*; his life is more precious than mine," and merged into asphyxia. Hartland soon followed suit, and these two were carried out by the only man left, a Purdassa. For this heroic deed, the man did not even get a bonus; as did the others, of half-a-month's salary. If Government have been so wanting in their duty, I do not think the Humane Society will be. If they hear of the occurrence, I am certain they will not fail to make private enquiry, and award their medals where so richly deserved. When the disaster occurred, the local Manager was on a holiday excursion, shooting. While the General Manager from Nagpore was frantically rushing about the pit's mouth, begging knowledge from those he met as to the state of affairs below, and supplicating all to go down and save lives, a little native boy, amid appalling scenes of death and disaster, was plaintively craving to be sacrificed in place of his master. After the accident, all lost their heads; no one attempted to go down; the fires were allowed full head-way, and the only means that could be suggested to improve matters was to stop the pumps, and flood the colliery. For part of a month, this process continued, and the flames were not got under. In despair, the authorities arrived at the conclusion that the only way of solving the difficulty lay in placing the matter in the hands of Mr. Foster, a mining engineer of the E.I.R., who has also theoretical and practical knowledge of machinery. And now a change came over the scene, and it is not too much to say that Mr. Foster has saved this undertaking.

He at once set the pumps to work full power, blocked up, even from the shaft's mouth, isolated and totally abandoned the lit seam at No. 2 (till the fires should be got under), shut off its communication with the connecting pit No. 4, and dug down through about 40 feet of sandstone to the third seam. He also instituted the system of air circulation now in vogue, under the able superintendence of Mr. Barnes, mining captain—a Newcastle man. When Mr. Foster arrived, the practical output was nil. In six or eight weeks, it was 900 tons daily, at which figure it stands at present. You will have but indifferently carried out your programme, if your visit does not include a look below; for this the manager's sanction is necessary, and it is generally courteously granted. The pit-mouth is elevated some 20 feet off the ground, and this admits of the little trucks being emptied into the waggons on the rails underneath. As you descend in the lift with a rush, a strange sensation creeps upward from the soles of your feet; you feel as if you were gently falling down, down, but before you have time to think, you have traversed the space, 180 feet, and are already standing in one of the passages at the bottom. The atmosphere is not, as one would imagine, cold, but about the same as the temperature above. The drip, drip of water, its murmuring flow to the pumping dips, the walls of black, the gloom made palpable by the flickering lights, the damp, clammy look and feel of all around you—are not prepossessing in your first experience of cavernous depths. As you get away, however, from the shaft, matters mend, and now whitewashed walls, pathway and ceiling with many bright lamps about, make you fancy you are going through clean masonry tunnels. Not far off is the cabin; a good door leads into it, shining white with a new coat of lime. There are benches, and pegs to hang your coat and hat on; a clock is there also, and the place is dimly lighted. Here you disrobe and the stay is short, "to get your eye-sight," as it is called. In this neat little box, with 200 feet of ceiling and thousands of miles of wall and floor, one ought to feel secure. The mining captain, to whom you have been made over, kindly explains, as you proceed, the system of air circulation, and at the zinc doors, half shut and with tarpaulin screens, puts down his lamp to gauge the current.

I may here briefly explain the mode adopted of supplying the workings with fresh air. The main cause of the current is the furnace at the bottom of the shaft. This, sunk to below the seam, is partitioned off down the centre. The in-blast goes down the open part, and the return air up the portion screened off. The air descends, and is conducted to where the miners are at work by shutting off its passage into the worked galleries where no men are. From the shaft on the four sides, galleries or passages are cut, 18 feet in width and 45 feet blocks of coal are left to support the roof; then a gallery, excavated at right angles, 10 feet in width; then a line block left, a gallery cut, a block left, and so on, till the seam is at fault. All these passages, worked or not worked, if open, would convey the fresh air through them, and exhaust it; so, as these square workings are completed, the air must be shut from them to feed the parts being worked. Doors are put up and tarpaulins hung to regulate the draught, and

innumerable passages are blocked up with shale. After the air has fed all the necessary parts, it becomes hot and effete, and seeks a cold outlet to disperse itself of foulness, and dissipate its density, so it is led right round the working to the blast furnace. If the volume were let into the fire, it would extinguish it, and occasion a disaster, so it is taken above, over a masonry arch, into the hot ascending smoke, and fumes rushing up the part of the shaft partitioned. There is a strong draw created continually, and air sucked down by this simple means. There are no mechanical blast contrivances, and the work is done in a very efficient manner. When you consider that at each 45 feet there is a gallery at right angles to another, and these are continued in every direction in a network as far as the seam exists; and men are only at work at the further ends, it is, indeed, a most complicated matter both to give them air, and direct correctly the return blast, and only those thoroughly brought up to this work can solve this air problem. And Mr. Barnes, in charge of this intricate business, has lately come out from disseminating fresh air in dangerous and foul pits in the north of England, half-a-mile beneath the surface. As you make your way through the passages, little tracks of coal are continually being shoved along little lines down the centre, and on the side, water is flowing in a miniature stream. Further, and the air becomes denser, because there is no draught as yet, and there is a strong smell of powder from the blast shots let off. The whitewashed sides and roof give place to polished sparkling jet, jagged here and there, from which the water-drops glisten like gems, and every now and then the captain taps the roof to see where props are required. There are no safety-lamps used because there is no foul air (except when the coal is on fire underneath), and linseed-oil is only burnt. Now the wisdom of having disrobed is felt; you perspire at every pore, and the men are literally bathed in sweat. I am sure a course of this underground treatment would have a beneficial effect on fever patients who obstinately won't sweat. They (the miners) dig with pickaxes first right away under about 10 feet, a little above their sitting height; then the superincumbent mass is blasted down, after being notched above and on the sides, to direct the break. The seams of coal range from 9 to 13 feet, and there is only a thin belt of shale of about 6 inches running horizontally through them. The fuel possesses no free gases, and is on this account unadapted for lighting purposes, but it stands very high as a steam-producing agent. No. 2 pit is 250 feet deep; the third seam is being worked, and the output is 60 tons per day, which will be soon greatly increased. No. 4 is 180 feet deep, and has been worked for two years; its average outturn is 150 tons per day, and there are days in the month in which the work is performed altogether stopped. The yield from the latter pit (some days so much as 300 tons) is the largest of any single one in India, already with great promise of better results. The excavating work is all let out by contract; the contractors getting Rs. 1-6 for every ton weighed in the waggons. There is a third pit, as I stated above, in process of being sunk, but this will not be ready for another year. This colliery, with only two pits working, and one of them only partially, is turning out 7,000 tons a month, and the coal being sold at an average of Rs. 6 per ton, this gives Rs. 42,000. The working expenses at a rough guess are Rs. 4 per ton, so this leaves a monthly profit of Rs. 14,000. When pit No. 2 is at full work, and No. 5, the new one, also, which it should be a year hence, the three pits will yield 1,000 tons daily, and with the expenses greatly reduced, as will be shown, say to Rs. 3 per ton, the annual profit will not be less than 11 lakhs. With three sets of pits, in a few years, the undertaking could yield over 30 lakhs net annually. Mr. Reynolds, the present local manager, adds to other useful and amiable attainments that of a first-class mechanical engineer. His library is a perfect record and history of the metals, and all over his rooms, even from the most obscure places, Iron in Gold and Steel in Bronze stare at you from the backs of works by Bessemer and other eminent metallurgists. In such a steely atmosphere, it cannot be wondered at if the master has imbibed a portion of the rough qualities of his frequent mental food, which finds an outlet in his expensive practical hobbies of moulding, fitting, and blast furnace shops. The machinery imported is of the best and most costly description; as are the workmen brought on excessive wage from Ajmere and the Punjab. But casting on a large scale—18 blast-furnaces, and fitting appliances capable of manipulating the most intricate machinery—are surely out of place in a colliery, and these shops are now the load which is bearing to the ground this resuscitating industry. Mr. Foster has recommended the entire removal of these expensive whims, especially as all work for the colliery and railway could be done at Nagpore where labor is cheap, and where Government have large necessary workshops. With the removal of these workshops, if it is also decided to remove their creator to some sphere where his practical abilities will find legitimate scope, I think a new era will dawn both for the colliery and for the manipulation of the metals in India. Mr. Foster combines, as I have said, mechanical acquirements with mining capability, and what he has accomplished in so short a time in retrieving an almost ruined industry is a sure earnest of what

he is able to do, and there is no question of his ability to carry the works to the most successful issue; and should the intention of Government of placing him here be carried out, it is to be hoped he will be directly under the Government of India, and not under the harassing superintendence of the local administration. So, in a few years, the accumulated burden on these promising mines will be removed, and this is no dream, but practically possible; and if the authorities have the slightest doubt on the matter, let them make over their property, including the railway, to the company desirous of taking it over, and an opportunity will then be afforded them of curiously contrasting the results of their departmental direction with that of private management. The railway also should be paying, as it has a large passenger and grain traffic, besides the coal; and Warrora stands first of the stations in the matter of export. The trade is gradually concentrating here, instead of the ancient mart of Hingunghat, which is 25 miles from here, and about the middle of the line. Warrora is a rapidly growing town with 12,000 inhabitants, and it little dreams of what it is destined to be as the centre of the black country of India, when the coal worked to purpose will create manufactories for the wealth of raw material.

H. T. T.

P.S.—The block of masonry and iron buildings at the colliery would now be worth about Rs. 60,000; the Attock engine a lakh, and the other machinery, including pumps, another lakh.

EDITORIAL NOTES.

MR. A. STORMONT, the Superintendent of the Khandesh Government Farm, in submitting the report for the year 1882, takes occasion to notice prominently Professor Pasteur's discoveries in relation to the spread and prevention of disease among livestock. The health of the herd, says Mr. Stormont, was generally good, the only disease appearing being four cases, (fatal of course) of black quarter inclining to splenic apoplexy. The victims were all yearlings occupying the same grazing ground, and the four deaths occurred within less than a week, two being on the same day. As the conditions popularly held responsible for the generation of this terrible malady were mostly absent, this peculiarly isolated cluster of cases must have been due to some accidental contagion, but from whence and how communicated it is difficult even to conjecture. Certain it is that the severe outbreak of two years ago was the disease's first visitation to this farm, and then not only were the carcasses deeply buried, but the surface ground all about the neighbourhood of the graves was purified by burning thorns and herbage; in fact, the disinfecting measures were so thorough that no trace of active contagion could possibly have been left above ground. Very recent investigations of great value have shown that even such precautions are only temporary in their results. Professor Pasteur of Paris, in his recent address at the International Medical Congress on Animal Inoculation, states that the *sporules* by means of which this splenic fever is propagated had lately been found by himself and others in a pit in which animals dead of the disease had been buried for 12 years, and that these germs by experiment had been proved to be as virulent as those from the blood of animals recently dead. He has also elsewhere demonstrated that these germs are brought to the surface in the economy of earth-worms, and that cattle, while grazing, by chance swallowing some of these, become the leaven of a fresh outbreak. But the mere clearing up of the etiology of the disease would be comparatively unimportant to agriculture, but for the cognate discovery that complete immunity from its infection is readily procurable by means of vaccination. The vaccine for this purpose is obtained by cultivation of the sporules found in the blood of an animal recently dead of the disease. Decoction of fowl has been found to be a suitable nutriment for these organisms, each generation as it ripens is applied to a fresh decoction, under certain conditions of temperature, and duration of exposure loses at each stage something of its original virulence. This series of successive attenuations goes on up to, it may be, the hundredth or thousandth operation, until the virus at last becomes null, and here the principle of vaccination is touched. Animals once vaccinated with this attenuated virus may with impunity come in contact with that of original virulence, or if they suffer from it, the effect will be of a passing nature, and not enough to cause death. The practical value of

this discovery has been placed beyond doubt by searching experiments, and even more so by its universal adoption in the French provinces. In the departments surrounding Paris no less a number than 20 thousand sheep, besides cattle and horses, were operated upon within the space of 15 days, and this limit was fixed only by inadequate capabilities of the Professor's laboratory. The vaccine is supplied to the public in bottles each, containing enough for 50 to 100 animals; it is injected under the skin on the thigh or other tender part with a small syringe, and no treatment is required for the pustules.

Mr. Stormont says that he has ventured to allude somewhat lengthily to this subject, believing it to be one of special importance to this country, where the disease is ill-understood, but so well dreaded, fraught as it is with such terrible consequences for the youth and cream of our flocks and herds.

THE following letter from Dr. J. Anderson, F.R.S., Honorary Secretary, Zoological Gardens, Calcutta, to the Secretary to the Government of Madras, explains the magnitude of the rabbit pest in New Zealand:—

The honorary committee for the management of these Gardens has received a pressing application for mongooses, with the object of introducing them into New Zealand for the purpose of destroying the rabbit, which in that colony threatens the very existence of the sheep farmer. Dogs, guns, and nets have been tried as a means of keeping down its numbers, but they have proved quite insufficient; and even, notwithstanding that during the year 1881, rabbit skins to the value of £57,000 sterling were exported from New Zealand, the threatened danger is still so serious, that it has been resolved to adopt some other measures, and to try, in the first instance, the introduction of mongooses.

It has been thought that the mongoose of the high region of Ootacamund (*Herpestes fuscus*) would be more suitable to the climate of New Zealand than the mongoose of the plains of India; and it has also been suggested that *Herpestes monticolles*, which inhabits the hill forests of Southern India, more especially those inland from the Eastern Ghats, might be acclimatized in New Zealand.

The committee have been asked to supply 100 pairs of mongooses, and they now take the liberty to ask the Government of Madras to assist them in procuring as many as possible of the two species mentioned, for shipment in the end of October from Calcutta. For any assistance in this matter, the committee will feel greatly obliged.

The Madras Government has ordered that every assistance is to be given for the collection and despatch of the animals.

THE Government Model Farm at Hyderabad, Sind, though the site is said to be the best that could be got near Hyderabad, as regards situation and soil, does not appear to be everything that could be desired. The farm is represented as "cut up by small kurriahs, bunds, &c.," and studded with brick-fields, besides being overgrown by "dub" grass, babool trees, and brushwood. Work was begun on the land on the 1st April 1881, and though bunds and kurriahs have been levelled down and filled in, trees and brushwood removed, brick pits and kilns dug up, and their adjacent rubbish cleared away and utilised as concrete flooring for farm buildings, it is estimated that several years of good tillage will be needful before the dub grass, whose roots form a regular net-work on the surface of the soil and reach to a depth of eight feet, is likely to be got rid of. This looks very like farming under difficulties.

The amount expended on ordinary farm work during the season under report was Rs. 1,610-0-10; on manuring for the current and following year, Rs. 72-3-4 were expended; and on dead stock, &c., and preparing the farm for cultivation, Rs. 2,124-11-10 have been paid, making a total of Rs. 3,807 expended during the year. The income is about the most unfavourable which the superintendent has ever had. The value of the season's crops amounts to only Rs. 772-1-2, and from all sources during the year Rs. 2,060-13-10 have been paid into the treasury, and there are still outstandings amounting on the 31st March to Rs. 2,378-8, including

the value of farm produce not sold up to 31st March, and rent of *salaru* farm land not credited to the farm before the above date. The low return obtained during the past *kharrif* season is chiefly due to causes, from which all cultivators in the neighbourhood suffered in a greater or less degree, as their crops happened to be early or late.

The very promising vernacular agricultural class for seminarians we briefly noticed in our previous issue.

WARADI cotton is, in the opinion of Mr. Strachan, the Superintendent of Cotton Experiments, a less luxuriant variety of *compium indicum* closely related to the ordinary Sindi plant. It will not, however, yield so much clear cotton per acre as the common Sindi does. Both varieties are short stapled, and are equally useful for spinning purposes when mixed with cotton of longer staple. With regard to Bamieh cotton Mr. Strachan says:—"The few seeds of this cotton we had were sown along the sides of tobacco, &c., seed beds, and got in consequence more than ordinary attention; they were as usual healthy during the early part of the year, but at harvest time they behaved just the same as the ordinary Egyptian cotton plant has always done with me in Sind, the flowers or pods either dropped off or were attacked by bollworm. The yield was only a few ounces of bad seed cotton."

Cotton was the most extensive crop raised on the Khandesh Government Farm during 1881-82. In all, 152½ acres were laid down with the following result, which we take from the report:—

The total outturn of clean cotton was 15,916lbs., which quantity, divided by 152½ acres, the area sown (and therefore necessarily entered in the return,) gives 104½lbs. as the average per acre. This result, however, is not exactly correct, inasmuch as field No. 42 failed from drought, but subsequently yielded a crop of gram. Again, Nos. 41 and 45, which were partial failures, show yields respectively of only 30½lbs. and 45lbs., in addition however to the interstitial ambadi and other minor crops sown in the vacant ground. The effect of this correction is to raise the figures to 117lbs., an excellent general average for so large an area, and again an advance on that for the preceding year.

Some of the detail returns are yet more strikingly progressive, especially those of the Khandesh American, the best field of which yielded 228½lbs. per acre, another gave 221½lbs., and a third 204lbs. The average of these three equals a return of a bale of cotton to the 1½ acre, a crop which even a Georgian planter would hardly despise.

The American cotton was all cleaned by the saw-gin, and got into the market at an early date. The Hingunghat portion is also sold but not yet ready for delivery. The total value of the two kinds is Rs. 3,170 and of the seeds Rs. 530—total, Rs. 3,700, or a net return of Rs. 25½ from the acre of ground, being one rupee in advance of last year. The saw-ginned cotton was sold at Rs. 5 per khandi above the best local rate. It was known to be worth more than that, but rural traders naturally experience some little feeling of dubiety in venturing on an untried article, and I was particularly anxious to watch the consignment passing from hand to hand through the ordinary local course on its way to the exporter, whom it reached, carrying a value of Rs. 15 per khandi higher than good Khandesh, which brings it considerably above best saw-ginned Dharwar. The export value then of this staple is no longer a matter of uncertainty. The opinion of spinners and others from time to time quoted in these reports, and the sale at an enhanced price of the last year's entire crop, together prove beyond dispute that it is fully equal to what is known in the English markets as *middling Orleans*. But this quality even is capable of improvement; in fact, European consumers are yet ignorant of the wonderful extent to which India is capable of meeting even their most fastidious wants. The best of the cotton was picked and stored separately, and its seed as usual reserved for distribution, a quantity having been sent to Chandor to introduce the crop in that part. It is satisfactory to find that this annual supply of pure seed, aided by whatever of its successive produce the people themselves may have saved, is now perceptibly affecting the staple of the neighbourhood, inasmuch that the term

"Bhadgaons" is not uncommonly used as a standard by which to grade qualities of lower value. It is, on the other hand, the reverse of gratifying to find that so increasingly large a portion of the year's crop is badly mixed with inferior kinds, as the character and price of our cotton in the Bombay market must necessarily suffer in consequence, and as ordinary cultivators look forward with equal indifference to the development or extinction of the trade in even cotton, their richest crop, things are likely to go from bad to worse, unless some natural turn of the trade itself should bring about a regenerative influence. The introduction of the saw-gin would no doubt operate strongly in this direction, as the machine is not adapted to cleaning short-stapled cottons, the cultivation of which would thus be necessarily discouraged. It is, however, maintained by many well competent to judge, that the intelligent administration of a moderately stringent law is an indispensable safeguard to our great cotton industry, and it must be admitted that in the past two years' history of the trade, they hold a most powerful argument in support of their contention.

The General Committee of the Agricultural Exhibition which it is proposed should be held at Madras in the February of 1883, offer the following prizes for the under-noted essays:—

- | | Prize Rs. |
|---|-----------|
| 1. For an essay on water-lifts for use in different parts of India. Full details must be given regarding the cost and efficacy of each. It is desirable that drawings made to a scale should accompany the written account... | 100 |
| 2. For an essay on manurial substances—animal, vegetable and mineral—procureable in India. The report must especially notice those substances which are as yet unutilized in the agricultural practice of India. The probable cost of each manure when prepared for use, and the uses to which each is especially suited, must be particularly noticed... | 100 |
| 3. For an essay on the management of soils under coffee, or tea, or cinchona in this presidency, in view of maintaining their fertility... | 250 |
| 4. For an essay on the utilization of irrigation water, in view to obtaining the largest returns with the least injury to the soil, and least waste of water... | 500 |
| 5. For an essay on the best method of planting fuel plantations in India. Full particulars must be given as to the most suitable site for the plantations, their altitude, soil, climate, the varieties of trees, &c., with full details and cost of all operations... | 200 |

All essays must be legibly written on foolscap paper, and on one side only; they must specify the number and subject of the premium for which they are in competition; they must bear a distinguishing motto, and be accompanied by a sealed letter, similarly marked, containing the name and address of the reporter; initials must not be used. The copyright of all essays gaining a prize shall belong to Government. When an essay is not of sufficient practical use, the judges are not bound to award the whole, or any part, of a premium.

The detailed prize-list may be had from Mr. W. R. Robertson, Superintendent, Government Agricultural Farm, Madras.

The *Gardeners' Chronicle*, in noticing Mr. William Crooke's translation of M. Georges Ville's work "On Artificial Manures," has the following:—Physiologists, in the face of the conclusive experiments of Messrs. Lawes and Gilbert, will hardly agree with M. Ville as to the absorption of free nitrogen by plants, and as to the difference he draws between wheat, which absorbs its nitrogen in the form of ammonia; beetroot, which takes it as nitrate; and leguminous plants, which absorb it in the form of free gas, the verdict will be not proven. M. Ville advocates the use of what he terms a normal manure, comprising nitrogenous matter, calcic phosphate, potash, and lime; not that these constitute all that is necessary for plant-food, but the other ingredients are already in sufficient proportion in most soils. For practical and comparative purposes, careful experiments with various manures on the growing plants themselves are more serviceable than analyses of soil, or of the plant itself. To rely exclusively on published analyses, either of manures, of soils, or of plants, is to grope in the dark, because so little is yet known of the changes that go on in the plant itself. But

by experimenting in the way indicated, if we do not throw light on the method of operation, we yet gain results that are intelligible to all and beyond dispute.

The Government of the North-Western Provinces has, it appears, consented to take fifty copies monthly for distribution of the Meerut Agricultural paper, the *Mazhar-ul-Zuayal*.

The report on the cultivation of cotton in British Burmah for the year 1881-82 has just been issued. The total area under cotton during that period was 15,130 acres, or 198 acres more than it was in the preceding year. From experiments made for ascertaining the true yield of cotton-fields in British Burmah by actually weighing the cotton harvest on certain selected fields, it would appear that the average yields of fields wherever cotton is sown alone, is equal to 482lbs. of uncleaned, or 161lbs. of cleaned cotton per acre. In one district, Bassoin, where the testing was very carefully done, it was even higher. On *toungya* gardens, where other crops are also grown with cotton, the average yield was found to be 122lbs. of uncleaned or 41lbs. of clean cotton per acre. The experiments made this year are not conclusive, and the testing of the yield of cotton per acre is to be again tried with the current year's crop. For the year under review, however, the local Agricultural Department appear to feel themselves justified in taking 160lbs. as the average yield of cleaned cotton per acre for fields grown entirely with cotton, 40lbs. as the average yield per acre of cotton grown with other crops on *toungya* gardens.

The total yield of clean cotton during the year was as follows:—

| | | |
|---------------------|-----|--------------|
| Cotton fields | ... | 173,121 lbs. |
| Do. <i>toungyas</i> | ... | 561,920 " |
| Total | ... | 735,040 lbs. |
| or | ... | 6,563 cwts. |

The trade in cotton is confined chiefly to staple imported from Upper Burmah, the imports from whence have been as follows during the past three years:—

| Year. | By River. cwts. | By Land. cwts. | Total, cwts. |
|---------|--------------------|-------------------|-----------------|
| 1879-80 | 65,105 | 4,194 | 69,299 |
| 1880-81 | 9,400 | 284 | 9,684 |
| 1881-82 | 15,146 | 307 | 15,453 |

The cotton imported from Upper Burmah via the Irrawaddy during 1881-82, although considerably in excess of the quantity imported in the preceding year, is nevertheless valued below the imports of 1880-81. The 15,146 cwts. imported during 1881-82 is valued at Rs. 2,62,498, whilst the 9,400 cwts. imported during the preceding year is valued at Rs. 2,99,966. This depreciation in the value of cotton is ascribed to the fact of the crop in Upper Burmah not having been good. It would appear that the best quality of the staple was carried away to Western China through Bhamo, and the remainder, which was brought down to British territory, obtained comparatively low prices.

The quantity of cotton exported from British Burmah during the year under review was 20,553 cwts., valued at Rs. 7,36,782, against 18,684 cwts., valued at Rs. 7,38,965 in 1880-81, thus showing an increase in quantity of 1,869 cwts., and a decrease in value of Rs. 2,183. The depreciation is likewise due to the inferior quality of the article brought down from Upper Burmah.

Very little cotton was exported to the United Kingdom during the year, and the trade seems to be declining year by year. The exports during 1881-82 amounted to 1,126 cwts. only, valued at Rs. 16,741. The falling off in the demand is said to be due to the fact of the Burmese cotton finding no favor in the European market on account of its short staple, when cotton of better quality is obtainable from other countries. There has also been a falling off in the quantity exported to the Straits Settlements. The exports during the year were 9,740 cwts., valued at Rs. 1,81,163, against 13,099 cwts., valued at Rs. 2,61,844 in 1880-81. The decrease has, it is believed, occurred in consequence of the Chinese merchants having limited their purchases on account of the unsettled state of affairs in British Burmah during the time the monopolies were in existence.

The exports of cotton to the Indian ports during the year were as follow :—

| | owts. | valued at | Ra. |
|--------|-------|-----------|--------|
| Bengal | 4,394 | ... | 84,197 |
| Bombay | 4,068 | " | 72,207 |
| Madras | 39 | " | 750 |

There has been a very marked increase in the quantity exported to Bombay, compared with the exports of the preceding year. The quantity exported in 1880-81 was only 371 cwts., valued at Ra. 6,803; the exports of 1881-82 therefore show an increase of 3,697 cwts., valued at Ra. 65,404. The increase in the trade with Bombay is said to be due to shipments made on speculation in June by a few Marwarie merchants who had the opportunity of direct freights at low rates.

The somewhat unfamiliar-looking words, silo and ensilage, relate to an agricultural process which, according to its advocates, is destined to effect very considerable changes and improvements in some departments of the farmer's work. A silo is "a cistern or vat, air and water tight on the bottom and sides, with an open top, constructed of masonry or concrete, and it is used to store in their green state forage crops, such as corn, sorgho, rye, oats, millet, Hungarian grass, clover, and all the grasses." The fodder which is preserved in these silos is called ensilage. The fodder is cut, and instead of being dried according to the time-honoured custom, and then stacked, it is at once, in its green damped state, cut by a machine into pieces about an inch in length, placed in the silo, pressed firmly down, covered over with straw and with heavy stones or weights, and then left to ferment and solidify until required for use. When winter comes and ordinary green food is exhausted, cattle and other domestic animals are fed with the ensilage thus prepared. They take to it readily, relish it, and thrive upon it. Six cows which, when fed upon the ordinary winter diet of turnips and dry fodder, gave 30 quarts of milk daily, when fed upon ensilage gave 35 quarts, and not only so, but milk of better quality with thicker, richer cream, and yielding butter of excellent flavour and wholesome colour, such as can ordinarily only be obtained when the cows are out to grass. There are other advantages which specially affect the farmer. The use of the silo obviously makes him independent of the weather, or largely so, so far as gathering in and storing the winter supply of food for his stock is concerned. The system saves time, toil, and trouble, and promotes peace, plenty, and profit in a dozen different ways which we need not specify here, and, in short, according to its enthusiastic American advocate—a Mr. Bailey, who has tried it and published the results in a book—its adoption would introduce an agricultural millennium. A well-known French agriculturist, M. Goffart, has, it appears, carried on this ensilage system with great success; Mr. Bailey has achieved within the last few years not less satisfactory results in America, and in both countries others are following in their steps.

ARBORICULTURE.

COMMUNICATED.

(Continued from page 447, Vol. VII.)

FOR persons wishing to raise forest artificially, and not knowing what trees to select, I subjoin a description of some of the most approved trees well suited for cultivation in the plains of India.

I.—CLASS, DICOTYLEDONEÆ.

NATURAL ORDER, LEGUMINOSÆ.

Acacia Arabica (Willd.) ; *H. babool*, *B. bābā*.—The babool is well known to every one in India and highly prized. It is indigenous to India, stretching to Arabia, whence the name, and North and Central Africa. This tree supplies one of the true gums of commerce, extensively used in the arts and manufactures, also as demulcent in medicine. Babool is *arbuscula*, and not *arbor*, barely exceeding 80 feet in height with a trunk free from boughs of 40 or more feet according to its position, and girth at maturity of 10 to 12 feet near the ground. It is one of the hardiest of all timber trees we have in the plains. I have raised it very successfully on *poor sandy soil* near the Goomtee at Lucknow, and have found it growing on very high, hot, dry plains of many parts of India where other timber trees would be nipped in the infant stage and fail in after growth, and in moist land near the foot of the Himalayan Mountains where babool fares far better, growing very rapidly, and presenting a healthy appearance. Some babool trees, 15 or 16 years old, are still allowed to grow on the moist land near the Sarjoo which have attained the height of 40 feet and 4 feet girth in this brief space of time. I say "allowed," because the natives cut down babool at a much earlier age, hardly allowing 10 or 12 years' growth. At Lucknow two small babool plantations of about a quarter-acre

each, situated on the south bank of the Goomtee, near the O. and R. Railway line, are doing famously on sandy soil, having clayey sub-soil, notwithstanding the yearly rise of the river during the rains, which keeps three or four feet of the lower trunk buried under water for three or more days, without any injurious effect whatever on the trees. It is therefore clear babool will grow, because it is very hardy, on dry and high land and in the hottest part of India, but it prefers wet land and a humid climate, where it will grow to the best advantage. We have patches of land $\frac{1}{2}$, $\frac{1}{4}$, and in rare instances and localities one acre planted with babool, but fail to find hundreds and thousands of acres in one place planted with this really valuable tree. And then even these patches are denuded of the saplings after the 10th or 12th year. It is not understood why babool should not receive the universal appreciation in India due to it, when we know that its heart-wood ranks with *aloe*, but of a deeper colour, capable of receiving the highest polish, very strong, tenacious, durable, free from attacks of insects, withstanding decay under water, and not splitting under the strongest Indian sun; hence, in every way suitable for beams, rafters, doors and door-posts, furniture, cart and carriage wheels, well curbs of very superior order, farm implements of all kinds where wood is applicable, and for boat-building. This tree recommends itself also in the habits of growth of its roots; babool roots do not stretch sideways, but stretches straight down into the sub-soil in the longitudinal direction, which accounts for its being so very hardy, and requiring no care after the first five years' growth. During the first 40 years of its life babool grows very vigorously and attains its maximum height; it has then very little heart-wood, but mostly sap-wood of white colour. This sap-wood is far more durable and free from attacks of insects than many other sap-woods I know of. For this reason, and the short duration in which it is formed, the natives of India cut babool down and use the *kacha paka* wood (solid and unsolid). After the maximum height is attained the growth of the tree is confined in the expansion of its trunk, in the formation of the heart-wood—very slow process, because solid, extending from 5 to 700 years, when the tree attains the maximum size and quantity of heart-wood. The habit of the upper axis of babool is very branching and wide-spreading, requiring to be checked by close planting, gradually rooting up the surplus trees as the permanent trees advance in height. The bark and pods of babool contain tannin, useful for tanning leather. Goats are very fond of browsing on the tender branches and leaves, also the camels; the babool forest, therefore, in the infant stage, should be guarded from the depredations of these and other animals. The seed should be sown in June or July.

Acacia decurrens (Willd.) ; *H. bilati babool*.—Baron Mueller speaks in very high terms of this black-wattle acacia of South Australia. In the forest it is more lofty than *A. Arabica* in open localities, and equal to it if the latter be also in the same position. On account of its thick bark, this acacia has more tannin than all its companions, including oaks and many other trees; but its timber is inferior to that of *A. Arabica*, fit only for a few uses, but is undoubtedly one of the best woods for fuel. For supplying tanning material, forests of this tree might be formed to be rooted up when the bark contains the maximum quantity of the tan principle, reserving some trees for ascertaining the quality of timber at mature age. Regarding the large supply of bark obtainable from one *A. decurrens* full-grown tree, Mr. Dickenson states, that he obtained 10 cwts. or 1,120 lbs., which means 1 lb. 336 to 1 lb. 604 of tannin, the bark yielding, according to analysis made by Baron Mueller, 30 to 54% tannic acid, a quantity sufficient, according to some tanners, to tan 20 hides. It is noticeable that this tree, in its early stages, grows at the rate of about an inch in diameter of its trunk in each year (Baron Mueller). Like *A. Arabica*, *A. decurrens* is raised from seed sown in June or July.

Acacia dealbata (Link.).—This tree, called the Australian silver-wattle, is very valuable for many uses. Its timber is tough, very strong, and durable, therefore extensively used by coopers and other artisans, and as fuel of great heating power just suited to glass-manufacturers. The bark of this acacia is thin, affording tannin of less value than that of *A. Arabica* and *A. decurrens*. It is a pretty lofty tree, attaining the height of 150 to 200 feet in suitable localities. It likes humid soil and climate, will therefore grow to the best advantage in British Burmah, Lower Bengal, Assam, all along the foot of the Himalayan mountains, wherever the soil is moist, also on the banks of rivers in all parts of India. It is raised from seed sown in June or July.

Acacia fasciculata (Mueller).—A valuable timber tree of South Australia suitable for furniture, and other things requiring good wood which might be easily worked, receive high polish, and possess good appearance. In good soil it will attain, in the forest, a height of 100 feet. The seed is sown in June or July.

Acacia karroophylla (Mueller).—Native of South Australia, supplying bark for tannery, and excellent timber of brown colour for fancy turnery. This tree attains the height of 90 or more feet. Like all acacias, it likes humid soil, and supplies a large quantity of gum. The seed is sown in June or July.

Acacia leptocarpa (Benth.)—An excellent timber and bark-yielding tree of South Australia, useful for cabinet-makers and tanners. The wood of this tree is dark brown in colour, close-grained, firm, tenacious, and has yellowish stripes. Undoubtedly a very desirable tree for the plains of India. Raised from seed sown in June and July.

Acacia melanoxylon (Brown).—This is the best of all South Australian timber-yielding acacias. Its bark is useful for tanners, and the gum for technical uses. It attains the height of 80 or more feet, and the trunk is correspondingly thick. There is hardly any work belonging to cabinet-makers in which the timber of this tree cannot be used—from the highly polished billiard table and pianofortes to boxes, chairs, tables, picture-frames, railway cars, boats, &c., &c., are all made of this wood. This wood ranks in quality with the valuable walnut-wood. *A. melanoxylon* will grow very nicely in all parts of Upper India possessing humid soil, or on the banks of the rivers. It is very desirable that Lower Bengal, Assam, British Burmah, and Oudh should be well stocked with this really valuable tree. Raised from seed sown in June or July.

Dalbergia sissoo (Roxb.); *H. sissoo* or *sheesham*; the Indian mahogany.—Undoubtedly this tree is very valuable. In the forest it is pretty lofty, attaining the maximum height of 200 feet. The sap-wood of sissoo is valuable only for fuel, and for no other use; but the heart-wood, heavy, of deep brownish colour, strong, close-grained, tenacious, and finely laminated, is valuable for buildings, carriages, furniture, boats, farm implements, and various other things. The foliage of this tree is mucilaginous, and possessing demulcent properties, is extensively drunk mixed with water, steeped overnight with the admixture of a kind of sugar manufactured in Benares, passing by the name of *Kucha* or *Benarases cheenes*, for curing or alleviating venereal diseases by the natives of Upper India. Large forests of sissoo were found in the northern part of Oudh and N.-W. Provinces, especially in the Baraich district, which was once famous for sissoo wood, and has not altogether lost it yet, although the mature trees and forests are mostly gone, and used up without the precaution of planting new ones. At the present time mature sissoo is very rare, existing in out-of-the-way and unfrequented localities. Large numbers of young sissoo trees are to be met with on road-sides, in all districts of Oudh, and in some of the roads adjoining this province, in the N.-W. Provinces, planted within the last 40 years; but I have nowhere observed sissoo forests formed, whether in Oudh or in the N.-W. Provinces and other parts of India. The sissoo tree grows fast enough in height, but in girth and formation and concentration of heart-wood it is very slow. Some sheeshams, at Lucknow, planted 40 years ago when Oudh was under the native rule, have not attained the diameter in the stem of more than 18", which, excluding the sap-wood, would scarcely give heart-wood more than 9" diameter. Some sheeshum trees planted at Sitapore, in Oudh, in 1859, 24 years ago, have not attained a girth of more than 4 feet, but are sixty feet high. Sheeshum requires humid soil of the calcareous order, where it will form flourishing forests. This tree is raised from seed sown in June or July, for which purpose seed should be gathered in its maturing season—February to March.

Butea frondosa (Roxb.); *H. dhák* or *palás*. The dhák tree is very common in the plains of Upper India, especially in Oudh and parts of the N.-W. Provinces adjoining Oudh. The dhák tree found in open localities growing on, dry arid soil, is very different from the dhák of the forest;—in the former locality, it is a small stunted shrub, but in the forest I have found it growing 40 feet high, with a girth near the ground of 6 feet. The dried flower of this tree going by the name of *tesoo*, is extensively used in dyeing cloths and other stuffs requiring a yellow colour. A kind of astringent red-coloured gum or *vino* exudes from the bark of this tree, brought to use by the natives of India in separating the dye principles of indigo. The root bark is converted into strong ropes, and formerly made into *palúas* for lighting native matchlocks, when the muskets and rifles now in use were not to be found with the natives. The wood is reckoned as the best fuel, and its charcoal is used in manufacturing gunpowder. Dhák leaves are sold to native shop-keepers for packing articles, and in Hindoo festivities they are used as substitute for dishes, plates, cups, and saucers. This tree is raised from seed sown in June or July. Dhák is very slow in growth.

Acacia catechu (Drury); *H. khair* or *katha*. A middle-sized tree, 40 feet high, found growing on the outskirts of the Lower Himalayas. The Khair tree is nowhere cultivated, but is found exclusively in the forests. With the natives of India it is one of the most valuable trees, on account of the dry extract (*khair* or *katha*), whence the native names of the tree, eaten by them with the leaves of *Chavica betle*, in dyeing, and in medicine as an astringent. The extract is obtained by boiling chips of the heart-wood of this tree, and reducing and drying the extract. For economic purposes this acacia might be grown in northern parts of Upper India. When mature the khair forest will yield handsome profit to the owner. Except for the extract and as fuel, the wood of this tree is not valuable for any other use. Raised from seed sown in June or July.

Ceratonia siliqua (Linne).—The carob, or St. John's bread tree. A small tree, 30 or more feet high. It is extremely hardy, having been made to grow in very adverse soil and climate in India. It is a native of the Mediterranean regions. The carob tree is especially eligible for cultivation in our forests along the foot of the Himalayas. The value of this tree consists in the large quantity of edible saccharine pods it yields, resembling in value the dry dates, from which I could hardly distinguish it in taste. Baron Mueller, by analysis, has found 66 per cent of saccharine matter and gum in the pods of this tree. In Continental Europe the use of carob pods for feeding horses and all manner of agricultural live-stock is assuming immense dimensions; and in some localities live-stock are exclusively fed on the carob pod.

According to Baron Mueller the feeding value of carob pod is double of the best oil-cake having excellent fattening qualities. Forests formed of this tree will greatly profit the country in ordinary years by the nutritious food it supplies for the live-stock, and maintain them and starving people in years of scarcity. The pale-red coloured wood of the carob tree is valuable for many purposes and as fuel. The carob tree is raised exclusively from seed, which germinates very freely. The seedlings bear transplanting well; but for the formation of forest it will be better not to disturb the top root, allowing the trees to grow where the seeds are sown. I have grown and distributed large numbers of carob plants from seeds obtained from Malta, some of which, planted in the Agri-Horticultural Gardens at Lucknow, sown and transplanted 15 or 16 years ago, are now fruiting. These trees are growing on poor, sandy soil, and not flourishing and fruiting well. Carob requires rich calcareous soil and plenty of moisture. It is very slow of growth during its first five years; but when once thoroughly established, it is fast enough, growing into a pretty large widespread tree within the next ten years, producing abundance of sweet nutritious pods, not unlike, in appearance, those of the *Tamarindus Indicus*, bearing also the same quantity, or, even where properly taken care of, more pods.

NATURAL ORDER, EBENACEÆ.

Diospyros melanoxylon (Roxb.); *H. tendoo* or *abnoos*, the ebony tree.—A small tree 30—40 feet high with the girth nearest the ground of 4—6 feet, found growing in the forests of Oudh and N.-W. P., and other parts of India, in the same forest with *shorea robusta* and *terminalia tomentosa*. The ebony is very slow-growing, but lives to a great age. The heart-wood of this tree is jet black, solid, very heavy, strong, and capable of receiving the highest polish. This wood is called ebony, the generic term given to the heart-wood of many trees furnishing solid wood of peculiar structure. The sap-wood of this tree is also valuable. It is white, tenacious, does not split or crack under the sun, might be bent like a bow and not break, and is easily worked. It is much sought for handles of axes, spades, and for farm implements, wherever available. The fruit of *D. melanoxylon* supplies, on expression, a fluid which assumes a deep brownish colour, much used for varnishing the exterior surface of boats under water, and for fishing lines, to make them waterproof. It is a pity this valuable tree is not receiving the care and cultivation due to it, people near the forest ruthlessly cutting down small saplings for making handles for farm or other implements. Raised from seed sown in June or July.

NATURAL ORDER, SAPINDACEÆ.

Esculus Hippocastanum (Linne).—The well-known horse-chestnut tree of Central Asia. An ornamental useful tree 60 or more feet high, having stem measuring 18 feet in circumference. The seed of this tree forms food for domesticated animals, the bark is good tanning material, and the wood free from attacks of insects is used in making furniture. On account of its ornamental appearance the horse-chestnut tree is found in many gardens in the Indian plains. This tree requires humid soil and climate. It will succeed up to 10,000 feet in the Himalayan mountains, and flourish all over Burmah, Bengal, Oudh, and N.-W. Provinces bordering the mountains. Horse-chestnut tree is raised from seed sown in June or July.

NATURAL ORDER, MELIACEÆ.

Cedrela toona not taona (Roxb.); *H. toon*.—The Indian cedar. It is not known how this tree came to be called Singapore cedar. It grows wild in the Baraich district in Oudh within a radius of 40—45 miles south of the Himalayan mountains, ascending up to 8,000 feet in these mountains. In open localities, growing alone, the toon tree is very umbrageous and well suited for roadsides. But it will not grow everywhere. It requires a humid climate, and moist and friable soil, where it will grow into a majestic tree with deep green foliage very grateful to the sight. Under favourable and undisturbed growth, in the forest, the toon tree acquires a lofty height and huge girth—200 feet high, and near the ground diametrically measuring 6—7 feet. The slightly aromatic heart-wood has a beautiful light red colour and is finely laminated. It is much in request for furniture, doors, windows, inside of ships and boats of European make. Toon wood is

light, very ornamental, but not so durable, because not strong as the solid and heavy babool, sheeshum, and many other first class woods. It sells much cheaper than the woods before mentioned, but the large quantity of wood of a single tree, in value, exceeds that of these woods. Like the babool, toon is very branching and wide-spreading, requiring to be checked by close planting, to be gradually thinned out. Toon grows from seed gathered in February to March and sown in June or July. The flower of toon yields yellow dye used in colouring cloth, called hasante.

NATURAL ORDER, VERBENACEÆ.

Tectona grandis (Roxb.); H., sagon, B. shegoon.—The well known teak tree of Burmah. Slow but very valuable timber tree of lofty stature and huge girth, growing wild in Burmah. Straight as a rod, this majestic tree rises more than 200 feet from the ground, with the girth of more than 27 feet, growing thousands of years without showing the least sign of diminished vigour in growth. The value of the teak tree, as hitherto ascertained, lies in its timber used in shipbuilding, beams, rafters, doors, door-posts, furniture, railway carriages, and where plentifully to be had, sleepers also. Seed of teak tree has been imported into India from Burmah and trees raised therefrom, in the Botanical Gardens at Calcutta and Saharunpore, the Agri-Horticultural Gardens at Lucknow, Lucknow, and Lahore, the Wingfield Park at Lucknow, and various other gardens in India. These planted 25 years ago are seedling, from which plants have been and can be raised; but the trees themselves are mere saplings, 40—60 feet high, according to the nature of the soil and humidity of climate of the locality where they are growing, but they rarely exceed four feet in girth, which is mostly sap-wood with hardly an inch of heart-wood in the diameter. Teak braves the burning hot winds of the Indian plains, but does so at the expense of its growth. Lower Bengal all along the foot of the Himalayan mountains up to 6,000—8,000 feet above the sea are localities where, besides its native habitat, Burmah, teak will flourish well. Raised from seed sown in June or July.

(To be Continued.)

ON THE ECONOMIC VALUE OF THE JACK TREE.

(Communicated.)

NATURAL ORDER—*Artocarpaceæ*; *Artocarpus integrifolius*.

KNOWN IN BENGAL AS THE *Kanthal*.

ALTHOUGH this is a tree that is grown near to every ryot's house in Bengal, and in fact can be grown on almost any soil, provided the climate is not a very dry one, its value has, I believe, never been fully tested, and these lines are written with the view of attracting attention to it.

Belonging as the jack does to the bread fruit order, its growth, in a climate and on soil where the bread fruit grows, is only a natural arrangement, and there is little doubt but that the jack trees in Ceylon are about the finest one can see.

The jack tree is grown merely for its fruit, which all residents in India are aware is very large, very luscious, and has a very strong smell of over-ripe fruit which very few Europeans can appreciate, but which the natives revel in.

The wood of the jack tree is very like the mahogany in "grain," and were it not for its bright yellow colour, it would be a great favourite with cabinet-makers. As it is, jack wood is used largely for all domestic furniture, and when put through a process of staining, is greatly admired and always commands a ready sale. The jack trees in Bengal do not grow lofty, but they make up for it in girth, and planks 20 or 24 inches across, sawn out of jack tree bolls, are not uncommon. Some years back, happening to see a number of jack fruit taken off a tree while still unripe, I experimented with the milky juice that exudes from the fruit stem. I gathered the juice, and whipping it up like one does cream, I secured a viscid mass out of it that looked uncommonly like (caoutchouc) India rubber. This mass I put away in the shade to dry, and in due course I found it get hard and springy. I then got several ounces of this "caoutchouc," and with it moulded a cup and a vessel like a milk jug. These mouldings were quite firm, but at the same time very sticky. Well, to get rid of the "stickiness," if I may so term it, I used some oil, having for result a polished, smooth surface. I then placed the articles on the kitchen smoke flue, opening to dry and brown; unfortunately I was called away suddenly, and had to absent myself for two or three days, and as I had left no instructions regarding my "caoutchouc" vessels, I found on my return no vessels at all, but a mass of viscid, dark brown, thick *ayuppi* fluid not unlike varnish. Now, from this experiment I deduce that the jack juice contains a substance like caoutchouc—elastic, leathery, water-resisting, and capable of removing pencil marks. I had not the chemicals to test the qualities of the substance, and to compare the same with India rubber, and, therefore, I do not feel justified in calling it India Rubber.

I was careful to test the quantity I obtained, and on apportioning it to the number of fruits I tapped, I found that each fruit could yield fully two ounces of milk, and from it I got nearly one-and-a-half drachm of rubber (I use this term till another is found, or the substance is proved to be other than caoutchouc.) If this substance is caoutchouc, and each tree yields only 20 fruit, the result would be four ounces of rubber per tree.* I have not tapped the jack trees in order to continue these experiments; but I have not the least doubt but that they could be tapped as the rubber trees are done.

Now, if we look at the fruit of the jack, it consists of a number of "flakes," each flake covering a seed. This soft covering is very juicy and sweet, and if heated with water and allowed to ferment, then distilled, it yields a wine of fair strength, but rather strong flavor. I see no reason why, with the aid of certain deodorizers, this strong taste and smell could not be mellowed down, and a full-bodied mellow liquor, not unlike some of the Marsalas, be produced. Again, the seed, when roasted and ground down, is a highly nutritious article of diet, very like the flour made out of the Trappa by the Cashmerees. I believe it contains a very large percentage of starch, and as such, could be utilised in a variety of forms. Many of the common jack trees yield a greater percentage of seed than those that are more carefully cultivated, and I have seen 80 to 90 seeds come out of one fruit. If these seeds be taken to weigh a third of an ounce each, one fruit will give us 30 ounces of flour, and twenty fruits, the produce of one tree, 600 ounces = 37 lb of flour. Now, if we place the matter on a working estimate, it appears as follows:—

| Say two acres of land— | Rs. | A. | P. |
|--|-----|-----|-----|
| Rent at one rupee per bigha | ... | 25 | 8 0 |
| Ploughing, cleaning, &c. ... | ... | 20 | 0 0 |
| Seedlings ... | ... | 2 | 0 0 |
| Planting 27 trees ... | ... | 0 | 8 0 |
| Tending do for 48 months' at Rs. 4 per month | ... | 192 | 0 0 |
| Total outlay | ... | 240 | 0 0 |

Against this we have a plantation of 54 trees; say the fifth year we have eight fruits on each tree, this represents an income of $8 \times 27 = 216$ fruits. The sixth year say twice $216 = 432$ fruits, or in two years we have 648 fruits. These at two annas each for the eatable part of the fruits = Rs. 84 with 19,440 ounces or 1,215 lb of flour at 1 anna per lb, Rs. 70, and 1,944 drachmas or 121 lb of rubber = @ 8 annas per lb Rs. 60, or $84 + 70 + 60 =$ Rs. 220, and as the yield increases very largely in a very short time, the plantation will repay every expense and be self-supporting. Lastly, the 54 trees when they cease to yield, which may be at a time when they have reached a circumference of 9 feet, could be sold at Rs. 20 each for the plants they would yield, and may be looked upon as Rs. 1,080.

SUGAR-CANE CULTIVATION IN UPPER WESTERN INDIA.

(Communicated.)

IN the *Indian Agriculturist*, Vol. VII, No. 12, p. 449, there is an excellent note on the sugar-cane cultivation in the Thonegwa, Shweygyin, and Hanthawaddy districts in British Burmah, drawn out by D. M. Smeaton, Esq., M.A., B.C.S. This note deals very comprehensively with all points in sugar-cane cultivation as practised in those districts; but the *modus operandi* found in Burmah, as contrasted with those of India, being faulty, because the Burmese cultivation is found deteriorating the quality of the cane, easily ascertainable by the paucity of saccharine matter in the sap of Burmah grown cane, I therefore offer the following remarks, which includes a few hints about the manufacture of sugars of all kinds in the Indian method, in the hope of their being serviceable to sugar-cane planters in British Burmah and elsewhere.

In these parts of India sugar-cane is most extensively cultivated both for chewing or sucking, and for the purpose of manufacturing *goor* (unpurified dry saccharine extract), *rab* called in Bengal *ghora goor* (jaggery or crystallized and uncrystallized sugar not dried), sugars of various degrees of purity on the methods of native and European manufactures, treacle, molasses (*shira* H.), rum, spirit of wine, and vinegar. We have a large usine known by the name of Rosa factory, a few miles from the Shahjehanpore sudder station, in the N.-W. P., bordering the province of Oudh, where extensive manufactures of all kinds of sugar, treacle, rum, spirit of wine, and vinegar, &c., are made. The cane this usine consumes comes, principally, from the sugar-

* Caoutchouc, gum elastic, or India rubber is a milky juice found in many plants, but most abundantly in the natural orders, *Muriceæ*, *Artocarpaceæ*, *Euphorbiaceæ*, *Apocynaceæ*, *Asteriaceæ* and *Lupulaceæ*. The jack tree belongs to the *Artocarpaceæ*, and it is a question which experiment alone can decide whether rubber of sufficient economic value could be obtained from it. —ED., 1. A.

producing districts of Shahjehanpore, Sitapore, and Kheru, the latter two being Oudh districts, and next neighbours to Shahjehanpore. In addition to this usine, we have no end of sugar manufactures on the native style in tahsil Gola, District Khera, Sitapore, Bara-Bunki, Lucknow, and Cawnpore. The last three districts themselves produce very little sugar, but draw their supplies of unpurified sugar from Sitapore and Kheru, which these districts purify for conversion into *cheenees* of various kinds, *tand*, and *mirie*. Benares also manufactures much sugar, the unpurified supplies being drawn from the adjoining districts and from its own tahsils. In these parts of India the sugar-cane producing districts are, at present, for chowing or for sucking purpose, chiefly, Lucknow, Benares, Cawnpore, and Allahabad. In these districts, for sucking only, two principal varieties of cane are raised: the one has a yellow skin and when unripe green, and the other red. The former is called *Madrajes pounda* (Lucknow local name for Madras cane); and the latter *Bombaye pounda* (Lucknow local name for Bombay cane). These canes are thick, pretty tall (6'-10' high), each cane, including the tops (*agola*, H), weighing 2-4 seers of eighty tolas each, and are very sweet or comparatively insipid according to the amount of care bestowed on the cultivation, which includes, as a matter of course, proper soil and the quality and quantity of manure applied to the soil. No sap is ever extracted from these canes for conversion into sugar. It is, I believe, one of these two canes which is cultivated in Burmah. It is not known how these canes came to Upper India from Madras and Bombay, and from what length of time; but are in cultivation from some centuries back. The canes raised for manufacture of sugar are altogether different varieties. Two of them are raised—one is called *kagdi ookh*, *ikh*, or *ookhar*, and the other *dasse ookh*, *ikh*, or *ookhar*. The *kagdi ookh* is that principally raised and preferred. It is a thin slender cane, having yellowish thin and tender skin, can be crushed very easily with the rude appliances with the natives, less sweet than any kind of *pounda* (Madras or Bombay), 5-8 feet high, and weighing, on an average, 6-12 chittacks each (chittack=5 tolas). The other variety has a thicker stem, having greenish thick skin, of the same height, weighing each from 8-16 chittacks, less sweet than the *kagdi* variety; and some of them I have tasted, possessed alkaline taste, which comes, I believe, from their being raised on soil too rich in the alkali. In India the reason why *poundas* are not used for extracting sugar is not because of the paucity of saccharine matter in their sap—on the other hand they are much richer than the best *kagdi* and *dasse* canes I have tasted, but because the *poundas* command a high and ready market for chewing and sucking in the large cities in India, when each cane sells from 3 pies to one anna six pies, also because the canes being thick the native *kolhoos* are unfit for pressing thick stems.

The soil preferred for sugar-cane cultivation in these parts of the country is of a calcareous nature (*kankrita samina*, H.) having less humus and more lime. This kind of soil produces cane of the best quality, humus helping in augmenting woody fibre, and lessening saccharine matter in the sap. In Lucknow, however, the *poundas* are raised on poor sandy soil on the strength of the immense quantities of human ordure there available to the agriculturists at Rs. 3 to 5 per 100 ass-loads. After the proper soil is selected, mounds are raised, and four ploughings are given in the winter season, when the cultivators have finished their *rabi* sowings and are comparatively at leisure to attend to other works. Where manure is available the land is manured in various quantities in rural places with cattle-dung and ashes, and near the cities with human ordure. The ploughing and manuring finished, preparation for planting, in tracts embracing a large number of districts—Moradabad in the west and Jounpore in the east, including all of the districts of Oudh—commences in March; but in other places, such as Allahabad, Benares, and Azimgurh, from April to the middle of May. The seed-canes are first cut into small bits, each cutting having 3 to 5 nodules (leaf buds, H. *ankhwaj*) a foot long. Each seed-cane affords 3 to 6 such cuttings, the tops (H. *agola*), and the lower part (H. *jarila*), are rejected as unfit for planting purposes. While the canes are being cut, if sufficient hands are available, the land is partitioned, water channels provided, and beds struck out. If the land be found insufficiently moist, it is irrigated, and when of proper consistency, generally the next day or the day after, planting commences. Women, children, and men, *khoopees*, or any other implement akin to it, in hand, in a sitting posture, plant the cuttings in a sleeping direction, three feet from centre to centre of the cuttings in the same row, two inches deep, covered over with earth, and three feet apart from row to row:—thus an acre 660' X 66' having six partitions made by five water channels, 9 feet wide and 660 feet long, requires 3 X 220 X 63,960 cuttings obtained from 660 to 1,320 canes. Simultaneously with the planting of cuttings, are sown seeds of vegetables of the summer season, such as *khira* H., *shonha* B. (*Cucumis sativa*); *tarboos* H., *torboos* B. (*Miralis vulgaris*); *karela* H., *corchey* B. (*momordica charantia*), *ghya toros* H., *choondol* B. (*luffa aegyptica*); *ara toros* H., *jhingey* B. (*luffa acutangula*); *louti* H., *tao* B. (*lagenaria vulgaris*); *konara* H., *koomro* B. (*cucurbita maxima*); and in rare instances some of the summer greens known by the general name of *sag* of the natural order *amaranthaceae*.

When these latter have germinated, generally in a week's time, a watering is given; and weekly heavy irrigation is never withheld till the rains have set in. Before the advent of the rainy season, the appendages sown are in a fit state for sale, and are accordingly rooted up, and sold in the market, leaving the sugarcane plants standing alone, which, at this time, receive a hoeing with the spade, manured, if manure is available, and earthed up.

The proceeds of sale of the vegetables, in all cases, pay the cost of seed-canes, and that of cultivation up to the time the vegetables are rooted up. Nothing further is done to the canes after they are earthed up till the end of September, when the under dry cane leaves are extracted and used as ropes or strings for tying up the bunches of stems, for preventing crooked growth and falling down from heavy weight the canes acquire at this time, and in the coming two months. If the rains have not been timely and in sufficient quantities, artificial irrigation is resorted to, not more than two or three times, in September and beginning of October. This finished, the canes are allowed to concentrate the saccharine matter up to the middle of November, when canes are raised for sale in the markets for sucking; and up to the end of February, by gradually cutting from the beginning of December, when the sap is required to be converted into sugar, &c.

After the canes are cut the land is irrigated and properly hoed to admit of the stumps sprouting to supply seed-canes. Only those fields are irrigated for this purpose which have been harvested in November and not later than the beginning of December. This second crop of canes comes to the proper age for planting purposes by the latter part of March following: so that in India, within 12 months, we have two crops of cane—first crop for sucking or for manufacturing sugar, &c., and second crop for planting purposes. After the second crop of canes has been removed from the field, it is broken or ploughed up for some other crop. In India sugar-cane is never allowed to be grown on the same field two years successively, being a very exhausting crop.

Now, the outturn of a sugar-cane plantation is very various, no two fields producing alike owing to diversity in the cultivation, amount of care bestowed, and the quality and quantity of fertilizing matters in the soil. Each cutting grown into a bunch will produce from 3 to 15 stems of different heights and thickness, according to circumstances, containing 10 to 15 per cent. of woody fibre, 30 to 85 per cent. of sap, containing 10 to 35 per cent. of sugar, and the rest water. When cane-juice has only 10 per cent. of sugar, hardly any dry saccharine extract can be obtained, only molasses or very inferior dark-brown over-burnt jaggery can be had.

There are three reasons for the inferiority of Burmah cane—

(a.) It is harvested at a time (September or rainy weather) when the plants are growing, and the lowest percentage of saccharine matter exists in the stem.

(b.) The excessive humus in the soil on which sugar-cane is grown serves to augment the growth and quantity of woody fibre, and not the sugar.

(c.) The canes being planted on lands subjected to the tides, a great deal of water is absorbed by the plants which lessens the percentage of sugar in them, and the fertilizing elements of the soil which would form sugar are washed away with ebb tide, serving in still lessening the quantity of sugar.

I will now say a few words about the methods practised in India in the preparation of sugars, &c., by its natives, which I trust will prove interesting and useful to persons engaged in the sugar industry in India or in Burmah.

For manufacturing sugars, &c., the canes, tops cut off, are either passed between iron rollers (where Behesa mills are in use), or cut into small bits, by means of a chopper, *ganraes* II., of about 6' length, and sap expressed in the ordinary native *kolhoos*, which resemble, in most respects, the *kolhoos* of the *tees* or oil-*naan*. The sap obtained is strained through a clean cloth, and then boiled. A large *choolha* or oven is erected—more, if necessary, on the top of which is placed a large native-made deep plate-iron pan or *karkhi*, filled with the cane-juice and boiled. The fuel used is the crushed cane (*megas*) from which sap has been extracted. After a few hours' boiling, sugar crystals are formed, when, if *râb* is the object, the boiling juice is poured into clean earthen *ghurras*; and if *goor*, the boiling is allowed to go on till all water is dissipated leaving the residuum of a thick curd-like consistency, which is evacuated into shallow circular wooden or earthen pans, the inside of which has been well rubbed with mustard or rapeseed oil to obviate adhesion, to allow it to cool. When cool, in some places small lumps are extracted, shaped with the hand on a smooth wooden plank, pressed with the fingers and allowed to dry under shade. These lumps, weighing from 2 to 4 chittacks each, are termed *bhees goor*, most extensively manufactured in most parts of the N.-W. Provinces. Where *bhees* is not required to be made, as in Oudh, large deep circular wooden or earthen vessels are used, rubbed with oil as in the foregoing, filled with the thick residuum in the *karkhi*, cooled, and solidified. This is called *patra goor*; each huge lump, weighing from 10 to 40 seers, is called a *patra*.

The different kinds of *goor* and *râb*—some of which are of beautiful golden yellow colour, while others, dirty blackish-brown—are owing to two main causes. The first is that the

saps which have been reduced to *râb* and *goor*, in the one case were rich in saccharine matter, requiring little boiling and had, in some few and rare instances, undergone a little purification—cows' milk, and the scum taken off; and secondly, in the other case, saps contained less sugar, therefore much boiling had to be resorted to, also no purification was made.

Kand and *miesee* of different degrees of purification we find, are obtained from the stuff called *râb*, which are manufactured thus:—Huge baskets are provided, placed over *nândas*; if the quantity to be manufactured be small, or on *pucka* vats, if large quantities are to be obtained. In these baskets thick layers of river *wadda* (dried) called *sewâr* II., are put, the *râb*, after cooling, is poured into these baskets, and the tops covered. As is to be expected, the liquid uncrystallized sugar soon trickles down the bottoms of the baskets and collects in the *nândas* or vats. This is molasses or *shira*, H. When the molasses is well extracted from the sugar crystals, the baskets are opened, and sugar extracted. This is called *kand*, the shape, size, and weight of the *kand* depending on the shape, size, and holding capacity of the basket used. If *miesee* is required to be made, the *kand* is not allowed to dry, but boiled afresh with water and milk, the scum scraped off, and the purified liquid poured in earthen vessels of any desired shape, where the sugar crystallizes, and gets solidified. *Miesee* is highly purified sugar, and, some years ago, when the English sugar factories were not established in India, was much in demand for European gentlemen; but now the demand is lessened. The natives, however, like their native manufactured *miesee*, and prefer it to the best English sugar, on account of caste prejudice.

These are the principal native manufactures in sugar; *cheenees* and *shukkurs* are inferior sugars manufactured by the *hukasees* from *goor* by adding lime as a purifier, moistening the *goor* with water, scraping off the scum, drying and rubbing in a large *kurhai* by means of *kurchool* II., or large iron spoon. *Cheenees* and *shukkurs* contain both crystallizable and uncrystallizable sugar, especially those manufactured at Benares, known by the name of *Benarasee kacha cheenees*.

REPORT ON ALOE CULTIVATION AT THE CENTRAL JAIL, HAZARIBAGH.

THROUGH the courtesy of the Inspector-General of Jails and the Superintendent of the Hazaribagh Jail, we are enabled to present our readers with the following interesting report:—

The aloe (*Agave Americana*), a member of the natural order *Ameyllidaceae*, is a native of America, and has become thoroughly naturalized in countries bordering on the Mediterranean, in Africa, and in many parts of India.

Growth from seed.

It may be grown from seed collected from the tall, candelabra-like, stems thrown up by the plant after it has reached the age of from 5 to 7 years. The seed should be planted in a nursery of rows 18 inches apart, and the seed twelve inches from each other. The best time to plant them in Hazaribagh is during the rains, they will then rarely fail to germinate and throw out leaves 3 or 4 inches long by the end of the year. If, however, they are put in the dry season, they require watering at least twice a week. The young plants should be allowed to remain in the nursery till the following rains, when they may be transplanted to the hedge or plantation where they are intended to grow.

Growth from shoots.

This is the best method, because there is no chance of failure of germination. The labour of sowing is saved, and much time is gained. Young plants from one to two years old should be procured at the commencement of the rainy season, and put down where they are intended to grow permanently. If for hedgerows a ditch should be dug and the young plants put on the top of the earth thrown up, they should not be closer than 2 feet from each other. The holes in which they are placed should be 8 inches in depth, and the earth should be well pressed round them. No further care is then required, and in about three or four years the plants will grow quite close together and make an excellent fence. If it is intended to make an aloe plantation, the young shoots should be planted in rows ten feet apart, and five or six feet should be allowed between each plant in the rows.

Soil.

A gravelly or laterite soil appears to be best suited for the growth of the aloe plant. If the plantation is made on high ground, it is not necessary to make ridges to plant on, and the plant is quite prolific of young shoots, for experience has shown that they do generally well on the flat, but on low situations and hollows it is necessary to make ridges 12 to 18 inches high, the plant being very partial to a light, dry soil, while a damp and water-logged soil is death to it.

No manure is required, and it grows on the most stoney ground, where apparently there is not sufficient soil to support life in the plant. In some places it may be seen growing in the

cleft of the rocks. We have not found it necessary to hoe or dig up the land near the plants, and weeds, grass, &c., do not appear to interfere with its growth.

From experiments which have been made here, the use of the expressed juice of the leaves as manure has appeared to accelerate the growth of the plant.

Cutting the leaves.

The leaves should not be cut until the aloe is six or seven years old, after it has thrown up its tall candelabra-like stem. Some of these grow to the height of 18 or 20 feet; they flower and produce seeds; before these are thrown up the aloe is weak and not fit for manufacture.

Protection of plantation.

It is commonly supposed that cattle will not eat the aloe plant on account of its sharp-pointed leaf and acrid sap, but our experience has shown this to be an error. Several growing plants have had their leaves eaten, and very young plants have been found cropped close to the ground. It is desirable therefore to keep off cattle by means of a ditch (outside) and close aloe hedges round the plantation.

Value of crops per acre after the plants are 7 or 8 years old.

One acre of land may be expected to yield 7 maunds of fibre per annum, as it requires as much as 40 maunds of leaves to make one maund of fibre. There is no doubt about this, as repeated experiments have been made in this jail.

After the ground has been planted, no expenditure is required, and the cost of planting depends greatly on the distance from which the plants have to be brought.

Preparation of fibre.

After the leaves are cut, they are put through a crushing machine invented by my jailor, Mr. Dunn, which breaks the hard bark of the leaf and crushes out the juice. It has been found that a great deal of manual labour is saved by this process. The machine is not unlike a sugar-crushing machine. This process should be carried on as near water as possible. There the crushed leaves are pounded on a smooth stone with a wooden mallet until all the bark and woody matter are removed.

The fibre is then washed until the whole of the sap and dirt is cleaned out of it. It is dried in the sun, and is then ready for use.

R. COSS,
Superintendent.

CRITICAL NOTICES.

Elements of Sylviculture, a short treatise on the scientific cultivation of the Oak, and other hard wood trees. By the late G. Bagnieris, Inspector of Forests, Professor at the Forest School of Nancy. Translated from the French (2nd Edition) by G. G. Fernandes and A. Smythies, B.A., Indian Forest Service. London: William Rider & Son, 14, Bartholomew Close. 1882.

BAGNERIS' *Elements of Sylviculture*, though based entirely on the conditions of soil, climate and species peculiar to France, is nevertheless, we agree with the translator in believing, a work which may be studied with advantage by forest officers in every country in the world. The general principles implied in forestry are everywhere the same, and it remains for observers in every country to study the special requirements of the climate and the species with which forest officers have to deal. While, then, there is much in the book under notice which is inapplicable to India, there are very few of its chapters which will fail to interest, or from which useful hints may not be derived. Professor Bagnieris' manual was written mainly for the use of forest subordinates training in Forest schools, and brings together a mass of information which, as we have said, has special reference to France. The translators have done their work with care, and contented themselves with reproducing the original almost without note or comment. As themselves engaged in the Indian Forest service, an original chapter or appendix, or more copious notes with special reference to Indian requirements, would, in our estimation, have considerably enhanced the value of the book. In a comparison which is made between high forests and coppices in Part IV. Chapter I, the following interesting passage occurs:—

It is beyond dispute that in the same interval of time, high forest furnishes a larger yield than coppice grown under the same conditions; yet it is impossible to prove this rigorously, as it would be necessary to subject the same forest successively to these two separate systems. But observations tend to establish the truth of this proposition, which is besides an accepted fact among all foresters without exception.

Moreover, the produce of high forest has a wider range of usefulness. The quantity of large timber is more considerable, and volume for volume contains a smaller proportion of unsound wood. However, the question at issue concerns only the range of usefulness, since coppice standards, as compared with high forest trees, yield timber which is denser, stronger, and composed of better nourished tissue on account of the unhampered development

of their growth. For this very reason their wood is to be preferred in important constructions. On the other hand, timber grown under close leaf-canopy is in great demand for manufactures. It should be noted, too, that high forests which have been thinned, yield timber of medium density useful for almost all purposes, and lastly, it must be remembered that the consumption of manufacturing timber is far more considerable than that of building timber. Thus the superiority of high forest over coppice is completely established.

So far as fuel is concerned, coppice wood is better than the old trees of a high forest. But, on the other hand, the underwood of a forest under coppice is very nearly counter-balanced by the produce obtained from the thinnings made in a high forest towards the middle of the rotation.

Again, since high forest furnishes more considerable, as well as more useful, produce than coppice, it is evident that the revenue derived from it must be larger. But to obtain this larger revenue, it is necessary to accumulate a vast quantity of standing material, owing to which circumstance the ratio of revenue to capital engaged is small. This is equivalent to saying that those proprietors alone who do not consider their forests as a strictly pecuniary investment are interested in growing high forests, or in preserving those which they already possess, as such.

Lastly, a high forest, by the constant and complete manner in which it shelters the ground, ensures the improvement of the soil, and hence improved production in a higher degree than coppice. For still another reason, it can be shown that coppice is not so well adapted to improve the soil; it has been proved that the greater proportion of ash is found in young wood and in the outside layers of old trees; it therefore follows that repeated cuttings of the underwood impoverishes the soil more than would be the case in high forest worked on a long rotation.

From all these different points of view, it is evident that the private proprietor has no interest in converting coppice into high forest; on the contrary, it would be to his advantage to realise at once the standing material of any high forest he may possess and turn it into coppice. If he is owner of a forest of conifers, which is from its nature unsuited for coppice, he is always induced to limit the quantity of standing material to the lowest figure possible, and thus to adopt short rotations.

The State, on the contrary, has every interest in preserving its high forests, and even in converting its woodlands under coppice into high forests.

The chief reason why coppice is inferior to high forest is to be found in the shortness of the rotation. A single act of recklessness in the oft-recurring exploitations is enough to ruin a forest for several generations. The danger increases with the area cut every year. Certain forests there are, where the mischief caused by such operations carried on during a period of fifteen or twenty years, cannot now be repaired before the lapse of a century and-a-half. In a regularly worked high forest, on the other hand, when the rotation has been judiciously chosen and the blocks properly laid out, the damage caused by faulty operations is necessarily limited in area. Nothing short of the most careless thinnings can destroy the future of a crop, and regeneration cuttings must be very badly executed indeed for natural forces to be powerful enough to re-stock the ground with the valuable indigenous species, and to obtain amount of delay not exceeding a single period helping towards this end. But it is to be hoped that the progress of knowledge will continually decrease the frequency of operations executed at hazard or under a fixed idea.

There is an interesting supplement on the fixing of the dunes and the tapping of the cluster pine (*P. Pinaster*) for resin. A good Index renders the manual handy for reference.

The Mongoose on Sugar Estates in the West Indies. By D. Morris, M.A., F.G.S., Director of Public Gardens and Plantations, Jamaica. G. Henderson & Co., Jamaica.

THE substance of Mr. Morris' little pamphlet appeared in the *Field* some months ago. It may, however, be interesting to note the complete success of the mongoose as a rat-catcher. On sugar estates in the West Indies the mongoose has fully realised the hopes entertained of its usefulness. On estates where the mongoose was introduced in 1878, the following results were obtained:—

"In comparing the expenditure on an estate where I lived for some years, I find the present yearly expenditure for rat-catching shows £8, as compared with £80 spent in catching and poisoning rats, and rebuilding walls pulled down to catch rats. I take this from averages for five years before the introduction of the mongoose, as compared with last year's expenditure. This amount does not include the cost of poisons, baits, and traps, which would average fully £20 a year, making £100, as compared with £8.

"In comparing the quantity of rat-eaten canes destroyed before the introduction of the mongoose, I take the number of gallons of rum-cane ground during the crop preceding the introduction of the mongoose, and compare it with the quantity ground last year. This shows 14,650 gallons rum-cane ground before 1878, to 7,425 gallons ground in 1881; which, compared at the rate of seven loads of canes to a siphon of 450 gallons, shows eleven and-a-half hogheads of sugar spoilt before 1878, compared with five and three-quarter hogheads spoilt in 1881, taking 20 loads of good canes to the hoghead—or a destruction of 10 per cent. as compared with 5 per cent. under existing circumstances." Again: "Some of the best cane lands on the estate I have just mentioned had to be thrown out of cultivation for years, owing to the impossibility of saving the canes from rats. This land is now being taken up again and put into cane cultivation."

A correspondent in the eastern portion of the island reports that "On the four estates on the north side of the Plantain Garden River, they (the mongooses) have made a saving of 75 per cent. in the expense of catching rats; and it is only in public places, where the traffic of man and beast is about sixteen hours out of the twenty-four that ravages of rats continue. In the sequestered parts of the estates, where there happen to be any stone walls or buildings affording favourite residences for the mongooses, as they did formerly for the rat, and where the ravages of rats used to be greatest, I may say that the decrease of rat-eaten canes is, at least, 90 per cent." And he adds, "In a word, as a sugar planter, I feel most grateful to the mongoose and his importer."

Another in St. Mary's writes: "The mongoose has fully realised the objects sought by its introduction, and it has saved on this estate £50 in rat-catching expenses; and at least 20 hogheads of sugar (of the value of £10 per hoghead) per annum." A proprietor in St. James states that "the annual actual saving in rat-catching expenses and in rat-eaten canes on my estates, consequent on the introduction of the mongoose, has averaged from £50 to £200 at least, on almost every estate under my charge, according to locality." A correspondent in Trelawny writes: "I used to lose annually from 20 to 25 tons of sugar, viz., 500 cart-loads of canes (rat-eaten) were ground and sent to distillery. Last year, after the introduction of the mongoose, only one cart-load was so used. On two estates of mine in St. James, similar results ensued."

A large proprietor in Westmoreland writes to the same effect, stating that since the introduction of the mongoose, "rats have almost disappeared from my estate. The annual expenditure for rat-catching and poisoning was over £300; it is now nil. The rat damage to canes was very considerable: it is now inappreciable."

These extracts might be extended to include nearly every estate in the island, and with similar results as regards the benefits which the mongoose appears to have conferred upon the cultivation of sugar. The annual saving to sugar estates, by the introduction of the mongoose, might very fairly be put down at 90 per cent. of the rat-catching expenses, and at 75 to 80 per cent. of rat-eaten canes. This, according to the estimate given above, would represent a total saving to the island of nearly £15,000 per annum.

SELECTIONS.

ECONOMICAL MANURING.

LECTURE BY DR. AITKEN.

A LECTURE on the subject of Economical Manuring was delivered in Castle-Douglas Scotland lately by Dr. Aitken, chemist to the Highland and Agricultural Society, to a limited but most influential audience.

Dr. Aitken said he was pleased to find so many influential farmers before him. It would be his endeavour to show them as clearly as he could the best and most economical way of applying manures to the land, and he could not do this better than by showing them the character of the different kinds of manure which they were in the habit of applying. Formerly, he said, the object of the farmer was to get as much as he could out of the land, to extract as much as possible out of the soil, and to make that process last as long as possible. In those days the best farmer was he who was able to take most out of the soil. But the process of getting as much as possible out of the soil could not last for ever. The manure applied to the land was really a part of the substance grown upon it, for the farmyard manure was really that part of the crops which was not sold off. In a small chart displayed upon the wall was shown the loss which the farm sustained in nitrogen, potash and phosphoric acid during a four-crop rotation. It would be seen that there was on an average an annual loss of 87lbs. of nitrogen, 80lbs. of potash, and 25lbs. of phosphoric acid. These were not very much, and to some might seem very small. It was not possible to take out of the soil all they put in, and although those figures might seem very small, yet the constant drain of those substances would soon very materially affect the fertility of the soil. He then pointed out the loss sustained by the soil by the exportation of animals. In the chart before alluded to, it would be seen that the loss in nitrogen and phosphoric acid was high, and the loss of potash, lime, and magnesium was small. He showed that nitrogenous matter and phosphoric acid were being taken off the farm in the carcasses of animals sold, in a greater quantity than the potash; indeed, there were in the grain 33lbs. of nitrogen per acre taken off the farm, while in the straw there were only 12lbs. It was the same with phosphoric acid—it was high in the grain and low in the straw. It would be seen from these figures that farms suffered from want of nitrogen and phosphates rather than potash. Straw was rich in potash, and farmyard manure, which consisted largely of straw, was also rich in potash, while it was comparatively poor in nitrogen and phosphoric acid; therefore the application of farmyard manure was not always attended with the most satisfactory results. The farmer very soon found that some kind of manure containing phosphoric acid and nitrogen must be used to assist the manure from the farmyard to make up for its deficiencies. There are two ways in which the deficiencies of the farmyard manure might be made up. One was the using of mineral manures, and the other by using linseed or cotton cake high in nitrogen or phosphoric acid. There was no way of adding satisfactorily and

thoroughly, although slowly, to the fertility of the soil more than through the importation of feeding stuffs. It was frequently complained that the method was a slow one, and that it did not produce such brilliant results as mineral manures; but it suited light land better than mineral manures, and it would be able to tell its tale by and by, if not quite immediately. But it was important that they should have a ready return for the capital expended, and farmers liked to have a manure which they could count upon adding fertility to the crop to which it was applied. There were in the market, thanks to the energy of the manure manufacturers, an immense choice of various phosphoric and nitrogenous substances, and it became a difficult problem to the farmers which of those substances he ought to buy in order to produce the best results. The question was one very difficult to answer, because the application of manure depended very much upon the character of the soil, the character of the climate, and many other things, therefore it was of the utmost importance that the farmer should have some means of finding out for himself the best kind of manure to apply to his particular soil and climate, the best way to put it in, and the best time. Those were considerations which required very great care and attention on the part of the farmer, and which could not be fully explained by merely reading a book or listening to a lecture, but by practical experiment. Now, he would firstly deal with nitrogenous manures, as the kind which was of this first importance, as that was the substance not only lost to the soil by animal and vegetable exports, but also by drainage. There were three forms of this manure—the albuminoids, ammonia salts, and the nitrates. In farmyard manure a large portion of the nitrogen existed in the form of albuminoids, and when those were allowed to ferment they gradually became converted into ammonia salts, which in turn became converted into nitrates. The albuminoid matter took a considerable time to ferment, and the nitrogenous or albuminoid portion of farmyard manure did not yield itself up entirely to the crops to which it was first applied, as its beneficial results were not experienced until several years afterwards. Ammonia salts was the most concentrated form of nitrogenous manure, and was not so easily washed out of the land. It had to be converted into nitrates before the plant used it, and before it was liable to be washed out. It was converted into nitrates owing to the action of a germ, or small organism which was busily engaged in the fertile soil converting ammonia into nitric acid. This was very soon taken up by the lime, and in the form of nitrate of lime the plants were able to take nitrogenous food. But great care must be exercised lest the nitrates were not washed into the drains. Nitrate of soda very soon became nitrate of lime, and it was of the greatest importance that there should be a sufficient quantity of lime to assist in the conversion. If there was no lime, there would necessarily be a retarding of the process of nitrification. Ammonia salts were firmly retained by the soil—indeed, some soils retained it so powerfully that it could not be washed out. In the case of a clay land, or a land with a large quantity of humus in it, there need not be any great fear of the loss of ammonia. But when the ammonia became converted into nitric acid it had a great tendency to find its way into the drains. In applying ammonia salts we had to consider how long the ammonia required to lie in the ground before the plants used it. Nitrate of soda should never be put into the land except the plants were actually there, otherwise there was a great danger of the substance running into the drains. Those were general considerations, which might guide them as to which kind of nitrogenous manure to apply, and it would be seen by a little experiment how very marked was the difference in the power of the soil to retain the nitrogen in its various forms. Another question would present itself, namely, to what crop should a form of nitrogen be applied? It would be economical to apply to a crop with a long life a slowly acting nitrogenous manure such as dried blood, horn dust, and any other manure of that kind which are of the albuminoid class, and of a slowly decomposing nature. It required to be a long time in the soil before any result would be seen, or before it was converted into food suitable for the plants. Ammonia salts might be easily applied to strong land containing a large amount of humus before the time of sowing the seed, as it would be most disadvantageous to apply such a manure later on, because it was a peculiarity of nitrogenous manure that it was most wanted during the youth of the plant, and if it was late in being applied, it would perpetuate the youth of the plant and retard the time of ripening. The manure required to be applied so that it should come into contact with the roots of the young plants, therefore it should be put in the soil early. Nitrates acted immediately, and should therefore be put into the soil when the roots of the plants were grown and ready to seize hold of them. It would never do to put many of those slow acting manures to a cereal crop. If it were required to add nitrogenous manure to barley, it would be no use putting it in the soil in the form of 'shoddy,' or even bones, or blood, or any other slow acting manure, as it would not have time to decompose before the plant had reached the age at which it would be benefited by such manures no longer. Speaking of the cultivation of grass, Dr. Aitken recommended nitrate of soda, as the roots of grass retained it, and made it impossible that it should escape into the drains. Then as to phosphatic manures. There was a great variety of phosphatic manures, and they were sold in many different forms under many different names. Perhaps the most familiar form was the oldest of them all, namely, bones. Bones was a phosphatic manure, which differed from many others of its kind on account of its having nitrogen in its composition. It was a phosphatic and nitrogenous manure combining both those constituents, and it was an animal product, and corresponded with that which had been sold and carried off the farm. Bones had long been a very favourite manure, and were generally valued very highly; but in regard to them they had to consider several things. First as to the fineness of the bone.

It was well known, but perhaps it was not so well-known as it and ought to be, that rough bones, bones which were called half-inch bones, and crushed bones in bits varying from half-an-inch to an inch in length, were a very unprofitable form of application. He was recently at a farm where a handful of bones about an inch long were picked up, and which he was told by the farmer had been applied to the land by his father nineteen years ago, and there they were in a tolerably good state of preservation, showing that it was possible to put on that excellent manure in such a form as to make it not an economical manure. It was quite evident then that the finer the bones were ground, the more their surface was increased, and that would teach them that it would be much better to have them amply ground down. They were now beginning to understand that better, and to employ bones manure finely ground down. There was a practical difficulty in making fresh bone into a very fine powder. Even when very finely ground it contained a greasy substance on account of the oil that was in its composition, which kept it from rapid decay; therefore bones were a form of manure which they would not put on when an immediate result was required, but it was an excellent manure if they wanted an ultimate result. If they wished to improve grass then they would put on the crops preceding, or even the crops preceding that. A heavy manuring of bones might be applied to a turnip crop; then after that they could have a barley crop, and then a grass crop would greatly benefit by the bones applied to the turnip crop. There were two methods in which bones were manufactured for manuring purposes. First, the bones were subjected to a steaming process, and there was this fact that the process took out a considerable quantity of the oily matter, which enabled the phosphoric acid to be quicker in its action, and also enabled the bones to be more quickly acted upon by the plants. It put the bones into a more friable condition, so that the grinding bones by the steaming process, and the getting of them into a fine powder, was a matter for them still to consider. The more thoroughly they spread the powder, the more would the roots be benefited by the application. Another well-known method of overcoming the slowness of bones as a manure was to dissolve them, and that applied not only to bones but to every other phosphatic manure. There was one disadvantage which dissolving had in regard to bone, namely, that it destroyed the animal or the germ life which takes possession of the bone. The ordinary fermenting germs were readily destroyed, and they had no living fermentation in dissolved bones. What was known by dissolved bones was a manure which did not necessarily contain absolute bone. It was a name for all kinds of phosphatic manure which contained some bone or ammoniacal substance, and resembled the composition of what bone dissolved should be. They would see that there were plenty of ways of getting phosphates, and there were other and cheaper sources of albuminoid ammonia which might be added to it. It was quite probable that any imitation of dissolved bones was likely to be just as efficacious as the genuine dissolved bones. Having once put bones into sulphuric acid it was made not an organic substance but a chemical substance, and its special characteristic was gone; whilst phosphoric acid dissolved in that way would spread itself through the soil, and there was not the same fear of loss of phosphoric acid as of nitrates; in fact, it precipitates in the soil. Phosphoric acid was not easily washed out of heavy soils, but there were soils which did not so retain it, and would be a waste to apply dissolved bones to sandy soils, or to more approaching sandy soils. It was not, however, uncommon to have not only bones, which were an excellent application to a sandy soil, but also other phosphatic manures, reduced to an exceedingly fine powder, and applied to the soil without being dissolved. There had been experiments made where some insoluble phosphates had become useful for a crop, but these were few, and the general experience was that the dissolved phosphate was a better manure. There were some soils which were favourable for the application of undissolved phosphates, and those were soils rich in organic matters. It was extraordinary to find what results might be produced by perfectly insoluble phosphates put upon land rich in organic matter. The number of phosphates were very numerous, and farmers should be very careful in the phosphates they used for experimental purposes. Some phosphates go to a chalky powder, while others are, even of a gritty nature; but the more perfectly they were reduced to a powder the more certain was their action. Many of the discrepancies that had arisen in experiments with these manures had been due to the different forms in which they had been employed. It had been recommended and had been found beneficial to employ undissolved phosphates as a constituent of the manure heap. In choosing between soluble and insoluble, if they used the insoluble phosphate they did not put upon the land a large amount of sulphuric acid, for in all dissolved manures they were bound to apply a certain amount of sulphuric acid, but whether it did the land any harm or not was a question not yet solved. Some said sulphuric acid reduced the humus of the soil, bringing down the condition of the land and reducing its store of wealth. Potash manures were limited to three varieties, and their application was not so important as the application of the other two forms. It frequently occurred that farmers declared that potash was of no use to them. But sometimes it occurred quite otherwise. He had seen cases where potash had made a marked increase in the crop; therefore it was for the farmer to know when to use it. There was something for the farmer to learn in another respect, and that was the time to apply it. Sometimes potash did harm by reducing the crop, but that must be due to the time at which it was applied. The land did not permit potash to go away rapidly, or to be lost by drainage; therefore, there was no need for putting potash upon the land exactly at the time it was required by the crop. Dr. Aitken concluded by showing the doses required by land, and recommending that a committee be appointed for the purpose of organizing a series of experiments.—*North British Agriculturist.*

TO MAKE FOWLS LAY IN WINTER.

THE following is an easy and by no means costly method for obtaining a regular supply of eggs during winter, even when the weather is at its coldest. I cannot say that I invented it, but I can say that I have practised it for a great many years. As soon as the cold sets in, that is about November 15, observes M. Garnot, in a French paper, I have a quantity of hot dung carried into the poultry house, enough to cover the floor from 10 in. to 12 in. deep. This is beaten down firmly and left till about December 1; then every day for a month the layer of dung is supplied with a fresh layer of from 4 in. to 6 in. deep. At the end of this time the dung is turned over to mix it well by which means an increase of heat is obtained, thanks to the successive depositions and contributions of the hens whose perches are above. And so I reach the middle of January, when I have all the dung removed, and begin the entire process over again; and this carries me on to the first fine days. By this means I am able to maintain during the coldest weather a regular temperature, and I have the pleasure of obtaining fresh eggs at a time when they are exceedingly scarce. The expense of this method is merely the labour connected with it, and in winter time labour is not dear. The manure which I take away is excellent—very superior to that which I have at the beginning, because the fowls' dung is added to it day by day. In this dung, too, the fowls find a large quantity of worms, larvae, and insects, of which they are fond, and which they rarely get in winter time. I leave them at liberty to go out in the ordinary way; but they know that they should keep inside in unfavourable weather, and they stop and keep their feet warm on snowy days, when it is damp or when it freezes.—*Farm and Home.*

FOOD NOT FEATHERS.

THE *American Dairyman* has the following excellent article upon poultry, in regard to the present popular passion for breeding to feather to the sacrifice of useful qualities:—The chicken question presents an anomalous condition in this country. Wherever we go, north, south, or anywhere, we find farmers, merchants, mechanics, and sometimes even sailors, breeding poultry, contending at fairs, advertising through the papers, and raising a general hue and cry in behalf of their pets, and all on account of nothing on earth but the feathers. One would think from all the fuss that those people were breeding ostriches instead of chickens; that feathers were of more value in the market than flesh; that the American people preferred to wear feathers on their bodies rather than put flesh in their stomachs. Nothing finds favour with these chicken fanciers except the thorough-bred fowls that are simply bred to the feather. The size of the Brahma is sacrificed to the correctness of the tail and hackle markings. The Dorking has lost his breast in the struggle to preserve the flesh colour of the legs and the uniformity of the feather markings. How far this craze has gone in England we are not informed, but we know some of the best table fowls known to the trade originated there. In France not only are breeds of fine table fowls originated, but, according to all reports, they are still bred with an eye singly to table qualities; and not only this, but methods of feeding to the end of quick maturity, economy of flesh production, and perfection of flesh quality are closely practised and experimented with. The French seem to understand this question as a practical one, and go at it in a way to make fowls not only a pleasure to breed, but a profit to handle. Chicken food that is wasted by the ton in this country, as dead horses, stale bread, &c., is carefully husbanded and turned to the finest kind of chicken flesh in France. Our people are so fearfully squeamish about such things that, while they can stand and see the hen eat worms and carrion at her own sweet will, and chop her head off the next hour to put her in the pot, they will not hear of such a thing as feeding her on carrion as a business. The lady who eats the oyster raw from the shell is horrified at the Italian who does the same with the snail. It is a wonder to many people why Americans can succeed so well with fancy fowls, and yet meet with repeated and unvarying failure when they attempt to raise fowls for the market. In one they succeed, with the other there seems to be no profit. It looks as though the American character was built upon too large a scale to make a profit with fowls, unless he can get from 3 to 10 dols. a piece for his cocks and hens. No one seems to be able to reduce this thing to a purely business basis. It has been our pleasure to examine the equipments of many farms where it was intended to raise poultry on a grand scale; and generally, from the elaborate and costly fixtures, one would think the purpose was to raise children rather than chickens. It is very much to be doubted if a large establishment can ever be made a success from the start. Just as large oaks from little acorns grow, a large establishment must grow out of a small beginning that has developed a capacity in the owner for conducting a large business. We hope some day to see this; but not until the craze about colour markings has somewhat subsided.

INDIAN GARDENS.

IN addition to the gardens mentioned, there are the private gardens of Europeans living in India. Now, it might be supposed that in a climate and soil so favourable to horticulture, these would be first class, but such is not the fact. Anglo-Indians are ever on the move, and they don't care to go to the trouble and expense of laying down gardens for the people who come after them; still, in some places, the gardens—which are commonly called "compounds"—are fair enough. Desperate expedients, however, are

necessary to make English vegetables, which are the things most affected, flourish well. Thus, one will see an amateur gardener—a colonel or commissioner perhaps—gravely sticking little pegs of bamboo into his cauliflower stems, to prevent them curling Jack's beanstalk, and running up too quick; or a lady in her early morning *deshabille* carefully placing a lump of rock-salt at the roots of each asparagus plant, in the hope that so much kindness will induce the "grass" to grow. But gardening in India is not nice work for those who like to work themselves. Hideous grubs and insects are turned up with each dig of the garden knife with which we work, and sometimes the "malice," or native gardener, is a worshipper of the cobra, in which case that serpent becomes dangerously familiar, taking up his haunt near the well, and turning up perhaps when least expected. Squirrels devour one's peas, and white-ants eat everything; and, as the rule, English vegetables, except those grown at a great elevation on the hills, are tasteless, and scarcely worth the trouble bestowed upon them.

With regard to fruits, there are few of the indigenous kinds which are worth growing or can be improved. Mangoes take too long to grow to be worth cultivation in an Anglo-Indian's garden; whatever is done to improve this fine fruit is done by natives; but the Indian mango has still a huge and inconvenient stone, whereas the "high cast" Mauritius mangoes are said to have had their stones improved right away. One ingenious English gardener, indeed, attempted to grow very fine mangoes by burying all the dead pariah dogs that are killed once a year at the roots of his trees, but with what result is unknown. Mulberries, in some places, grow in hedges, but the fruit is poor. Guavas are capable of the "higher cult," but they are altogether in the hands of the natives. Oranges, except in some places, are also poor, and no attempt seem to be ever made to introduce the finer kinds, as those of St. Michael, Malta, or Seville. Melons are very fine, but a melon garden in India is a very different thing from a melon frame at home. In the cold weather, when the Indian rivers have run down, and leave great wastes of sand, exposed, the melon gardener plants his seed broadcast. By-and-bye the whole surface becomes a vast melon bed, and in the hot weather the fruit is sold at the equivalent of 1d. or less each. The melons of Cuddapet, in the Madras Presidency, are famous, but as the rule, Indian melons, like all Indian fruits, want new "blood" introduced, for the seed is too often worn-out. The Persian melons, green fleshed, are delicious, and easily grown, but are seldom seen. But it is a rule in India that whatever was good enough for a man's forefathers, is good enough for himself, consequently there is little horticultural progress. Pine-apples grow freely on the west coast of India, sometimes under the shade of the immense coconut groves of those parts, but are much inferior in size and flavour to the pines of the Straits of Malacca. The pine-apples of Singapore are, perhaps, the finest in the world; they are planted on the hillside in much the same way as they plant tea on the Nilghiris, and are to be purchased at merely nominal prices—one weighing several pounds can be had for a cent, or the hundredth part of a dollar; and the Straits pines enjoy the reputation of being so wholesome that they may be eaten to almost any extent with impunity.

There is a remarkable absence of fruits corresponding to our gooseberries, currants, strawberries, &c., in India. There are wild strawberries and raspberries, indeed, on the hills, but nothing resembling them on the plains. The fruits of India, like the flowers, seem to grow on large trees, and many of the commoner kinds, although eaten by the natives, are positively nauseous. In the jungles one sometimes comes upon trees loaded with fruit which looks good to eat, but which it is prudent to avoid. There is the jumbulum with its damson-like but disagreeable fruit; the nux vomica, which seems to bear oranges; the mowa, and many others. In the Malayan forests, however, mangosteen trees are very abundant, and it is a common thing to see the wild monkeys throwing this exquisite fruit down from the tree tops just like so many schoolboys up an apple tree. Once, when shooting on the Malayan Peninsula, my Malay "shikaree" gave me a peculiar and delicious fruit, of which I do not know the botanical name, and which I have never seen at any other time. It resembled a piece of honeycomb, but the cells were much larger. Each cell contained a sub-acid globe, of a flavour resembling the grape. Talking of grapes, the vines and the wines of Hindustan were once famous. Tavernier, Hamilton, and other travellers of ancient times speak of the red Indian wine on which, the Emperor Akbar used to get royally drunk. But wine is never seen now; at least wine of local manufacture. The Indian wine seems to have shared the fate of the Persian wine of Shiraz, which in the earlier days of our occupation of India, was thought so good that it was drunk at the tables of the English merchants at Calcutta, though wine is still made in Afghanistan, and the Emperor Baber thought there was no better. His memoirs contain many interesting allusions to it. But there is a prospect of India producing wine before long. The Maharaja of Cashmere has imported champagne and Burgundy wines, as also French vine-dressers, and his experiment is said to give promise of success. Remembering the ravages made by the *phylloxera* in the vineyards of France, the Maharaja ought to realise immense profits should his champagne equal that of Epurnay. Grapes will grow well in many parts of India, even in the hottest places, but they are mostly white—of the Sweetwater kind. Purple grapes, dwarfed in the Japanese fashion, and grown in pots, are to be seen in some places, and are exceedingly quaint and pretty, the huge bunches of purple fruit appearing so very much out of proportion with the stunted vine that bears them.

Something may be said here of Indian gardeners, or "malices" as they are called. Their cheapness is perhaps their greatest recommendation. Remembering that an ordinary gardener's wage in England is something like £1 a week, it is refreshing at first to have to pay a "malice" only 10s. a month, but then the difference! The latter is a most unteachable person, and he is full of crochets

and crudities. Worse than all, he is, as a rule, a humbug and a thief. If there is any choice fruit or vegetables about he will sell it in the bazaar, and say the squirrels or bandycoots ate it. One thing only he excels in, and that is the making of bouquets. Natives generally have a wonderful taste in arranging flowers—or shall I say, colours?—and their bouquets are masterpieces of floral art. Every native "malloos" has a garden within a garden—a garden of his own. In this he cultivates, at the least possible trouble, chillies, cucumbers, vegetable marrow, egg-plant, and such-like curry stuff, for himself and family. His melancholy song or wall, as he draws the garden water by buckets from the garden source or well, is familiar to all Anglo-Indians, and can be recalled, however far from India they may be, by the slightest effort of the memory.

But gorgeous as are the Indian flowers in their flaming scarlet, crimson, and yellow colours, there are no flowers in India, after all, to be compared, for simple loveliness, with the wild flowers of the English spring. The pink and white hawthorn, the violets and daffodils of our hedgerows, are worth them all put together when the lark is singing in the sky, and Nature's beauties bring the recollections of our happy childhood vividly before us. Nor is there anything in India to surpass a pear or a cherry tree in full blossom. The "Gold Mohur" and the Hongainvillea may be more dazzling, but they are certainly not so lovely or so sweet. And let this fact act as consolation to those stay-at-home people who are disconcerted with their own modest English gardens because they imagine tropical plants are so much finer than anything they can grow there. It would be unfair indeed to say that Indian gardens have not a beauty of their own, but it is what the French call the *beauté du diable*—gaudy, meretricious, fantastic. One can love English flowers however humble they may be; but admiration at the best is all one can give to an Indian garden.—*F. E. W. Gardener's Chronicle.*

THE CULTIVATION AND QUALITIES OF ENSILAGE

SEVERAL correspondents having recently recorded in the columns of the leading journal their experience and observation of this new article of food for stock, as cultivated in France and in America, including a long article from Professor Thorold Rogers, Sir J. B. Lawes, Dr. Voelcker, and Dr. Lyon Playfair have lately written on the same subject. From their contributions we make the following extracts, beginning with the hon. baronet, who writes:—'Granting all that has been said in favour of ensilage to be true, its importance is not quite the same to the British farmer as it is to those who farm in France or on the other side of the Atlantic. The main object of ensilage is to secure a succulent food for consumption during the winter months. In the agriculture of the States and of France, such roots as mangel and turnips do not appear to occupy any important position as regards winter food for cattle. In the States—where the statistics relating to the area occupied by the general crops are collected and published—no mention is made of either; and in answer to inquiries on the subject, I was informed that the acreage grown was too small to be reliable. Unless, therefore, it is proposed that our farmers should place their roots in a silo, or substitute for them some other green crops, their interest in the value of ensilage differs very materially from that of those who live in countries less favourable for mangels or turnips. We have a succulent food of the best possible description already, and, if anything, we rather require a dry substance to mix with it than a still larger amount of succulent matter. The question, therefore, as far as we are concerned, is considerably narrowed. It does not affect those who make hay for sale, nor those who feed their grass, clover, or tares, in the summer; it merely affects those who convert a portion of their clover or meadows into hay for their own consumption; and it is a question for them to consider whether, on the whole, ensilage can supersede haymaking with advantage. No information on this point is given in the article on ensilage published in the *Times*. We are told, indeed, that the stock ate the food and thrive upon it, but we are not told what was the amount of loss attending the process itself; or, in other words, for each 100lbs. of sugar, starch, and other digestible product put into the silo, how much came out?'

Sir J. B. Lawes is afraid of this loss in the silo, and refers to an American writer who states that Indian corn containing 5 per cent. of ash, when put in the silo, contained 0 per cent. when taken out. This he calculates to amount to a destruction of 40 per cent. of the vegetable matter, unfortunately, too, of the substance of the highest feeding value. This loss may be exaggerated, but Sir J. B. Lawes thinks it should be decided by experiments, as also the cost as compared with haymaking; and until this is done, recommends the British farmer to wait.

Professor Voelcker, F.C.S., writes:—'The object of ensilage is to preserve succulent cattle food which, like maise out green, is incapable of being preserved economically by the ordinary processes of drying. In many parts of the Continent, and more recently in America, where ordinary English fodder crops cannot be grown and preserved in the field for winter use, recourse is had to ensilage of crops such as maise or sorghum. The summer temperature of our climate renders the profitable growth of such crops too uncertain for any farmer to depend upon. It must also be borne in mind that ensilage is not practised even on the Continent or in America for the conservation of grass or other equally succulent foods without the admixture of a considerable proportion of chopped straw. Grass of fair average quality by itself is not put into silos in these countries. According to the more or less succulent constitution of the green food, such as maise or sorghum, from 10 to 30 per cent. of chopped straw has to be mixed with the succulent food before it is pressed down in properly-constructed, walled, covered, and perfectly water-tight pits. Without the admixture

of chopped straw or similar dry materials, grass placed in silos, according to my experience, derived from the examination of specimens which have been sent to me by experimental agriculturists during the last few years, turns into a sodden mass of repulsive smell and taste, resembling more rotten farmyard manure than feeding materials. During a discussion on ensilage at Boston, Massachusetts, in 1880, Professor Guzman stated most distinctly that, in his judgement, there had been no improvement over the old plan of making hay when the sun shines. Sir John B. Lawes directed attention to the great loss in sugar, starch, and other nutritive substances under favourable circumstances. I fully endorse his views, but would add that under adverse conditions the loss in the elements of nutrition will be still greater, and ensilage under such conditions may prove a complete waste of food.'

Professor Thorold Rogers, replying to Sir J. B. Lawes, says:—'I should not presume to argue on practical agriculture with an eminent authority as Sir J. B. Lawes, but I am as a loss to understand how he has concluded that so much loss on the given article could be resultant from storage in a well-constructed, properly-covered, and adequately weighted silo. The object of silo storage is the preservation of the article in a state as nearly like green forage as possible. Some slight fermentation there is, but there is little or no heat, and, as I was told, little or no evolution of carbonic acid. As to the greatly increased yield of produce from the food given, they who give testimony are unanimous. I saw the cattle, inspected the dairy produce, and learned what was the monthly yield of milk by cows fed on the system.'

Dr. Playfair says:—'For the last three years I have taken much interest in the progress of ensilage in the United States. This system of preserving food for cattle progresses with great rapidity, and this fact alone, in a country of such practical aptitudes, shows that it deserves careful attention. No doubt exaggerated estimates of its value prevail; but, with due allowance for these, the results are remarkable. My friend, Colonel Cannon, a well-known breeder of shorthorns in Vermont, has taken up the system with much caution in comparative trials of the new and old system of feeding, careful records of weights being preserved. So far as these have gone, he obtained an advantage of about 8 to 10 per cent. in the feeding power of the silo food. But it has various incidental advantages which induce him to give a large extension this year to his experiments. In fattening cattle, or in feeding them for dairy produce, it is of importance to induce the cattle to eat as much as they can properly assimilate. Now, if silo food and the ordinary food be put into the same trough, the cattle in all cases in which I have seen the experiment tried, take the former instead of the latter. To preserve food in silos many precautions are necessary, and I should be sorry to see our farmers rushing into the system with their limited experience. When carefully conducted, I have never seen a failure; though, on the other hand, I have seen putrid instead of preserved food turned out of imperfect silos. The greatest success has been with Indian corn, which is put into the silo just as the ears are being formed. My only knowledge of agriculture is scientific and not practical, and it will be for practical farmers to tell us whether, even with the vicissitudes of our climate, there are not certain parts of England which could grow this profitable crop up to this stage of its maturity.'

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The usual Monthly General Meeting was held on Wednesday, the 29th November 1882.

W. H. COGSWELL, Esq., President, in the Chair.

The proceedings of last meeting were read and confirmed.

The following gentlemen were elected members:—

Dr. J. B. Rudduck, Messrs. F. Wood and J. P. Scotland, and Baboo Pertab Narain Sing.

The names of the following gentlemen were submitted as desirous of joining the Society:—

M. Brown, Esq., Manager of the Sungma Tea Association, Limited, Darjeeling,—proposed by the Secretary, seconded by H. J. Leitch, Esq.

Manager of Woodlands, Cachar,—proposed by the Secretary, seconded by W. S. Crosswell, Esq.

Alexander Maun, Manager of the Nona Tea Company, Assam,—proposed by G. U. Yule, Esq., seconded by W. S. Crosswell, Esq.

Manager, Otter Indigo Concern, Tirhoot,—proposed by the Secretary, seconded by R. Blachynden, Esq.

Thomas B. Walton, Esq., Manager, Equitable Coal Company, Limited, Seetarampore,—proposed by the Secretary, seconded by R. Blachynden, Esq.

Major R. Bartholomew, Deputy Commissioner, Jhang,—proposed by F. W. Tytler, Esq., seconded by H. A. Firth, Esq.

Major Duncan G. Pichey, Cawnpore,—proposed by H. A. Firth, Esq., seconded by the President.

Sheikh Gholam Moheed-ood-deen, landed proprietor, Meerut,—proposed by the Secretary, seconded by Raja Suttayanund Ghosal.

His Highness the Nawab of Jaora,—proposed by the President, seconded by Raja Suttayanund Ghosal.

His Highness the Raja of Narsinghgar, Bhopal,—proposed by the President, seconded by Colonel W. Kincaid, as a life member.

Rejoined—G. W. Shillingford, Esq., Bagraote Pillans Hat, vid Silligoree.

CONTRIBUTIONS.

From the Government of Bengal—the Annual Report of the Government Cinchona Plantation in Bengal, for the year 1881-82, and the Annual Report of the Quidologist for 1881-82.

From the Government of Bengal—Report on the Administration of the Registration Department in Bengal, for the year 1881-82.

From the Smithsonian Institution—The Annual Report for 1880.

From the Editor—The *Tropical Agriculturist* for October and November, 1882.

From the Editor—Journal of the North China Branch of the Royal Asiatic Society for 1882.

From the Secretary—Journal of the Asiatic Society of Bengal, Part I of No. 11, 1882.

Proceedings of the Agri-Horticultural Society of Madras of 6th September 1882.

From Dr. George King, Superintendent, Royal Botanic Garden, —presenting ten plants of *Musa Textilis*, for experimental cultivation in the Society's Garden.

COMMUNICATIONS.

Japan Pea.

Letter from the Government of India with papers regarding the Japan Pea, and China Bean, the Soy Bean, alluded to in the proceedings of a meeting of this Society, held on the 2nd September 1881, as also Resolution thereon to the effect that the Government think it desirable that the cultivation of this Pea should be extended in this country, and stating that a fresh supply of seed will be procured from Japan, in order that further experiments may be tried.

BEE-KEEPING.

Letter from the Government of Bengal on the subject of Bee-keeping in India, and enquiring whether the Society can afford permission to Mr. Douglas, who has brought out some hives, to keep them in the Society's grounds at Alipore.

A reply has been sent that the Society will be happy to meet this request, and to afford Mr. Douglas every assistance in their power.

ALOE FIBRE EXTRACTOR.

Letter from the Government of Bengal, dated 18th November, intimating with reference to a previous communication of the 25th August 1881, that a model of the "Mexican Aloe Fibre Extractor" has been despatched to the Government of India, and that the model will be forwarded to this Society on receipt.

Letter from Mr. H. Preston, Director of the Botanic Garden at Trinidad, dated 26th September, accepting the Society's offer for an exchange of plants and seeds. Advises the despatch of a case of West Indian plants, and hopes shortly to send some roots of the *Arachaca Edulis*, in regard to which he writes as follows:—

"I have to obtain them from some hilly district on the main. It is very rarely brought over here as a vegetable. Indeed in Venezuela where it is collected it does not receive much attention."

SORGHUM.

Letter from Major Pitcher, Assistant Director, Department Agriculture and Commerce, N.-W. Provinces and Oudh, dated 9th November, forwarding sample of *goor* manufactured at the Cawnpore Experimental Farm from amber-colored Sorgho, also specimen of pulp prepared at the Lucknow Paper Mills from the refuse of the stalks, and soliciting opinion on these samples.

The following report kindly prepared by Mr. W. H. Cogswell, with reference to the above, was submitted to the meeting:—

"The samples above referred to are worthy of consideration, both being products of some value, if properly and carefully prepared.

"The plant is well known, Sorgho of Sorghum, the seed of which yields a hard food-grain, capable of being ground into good white flour. It is also used for cattle feeding purposes, the green fodder of the plant being highly nutritious and sweet.

"The sample of *goor* said to have been prepared from the expressed juice of this plant is very soft, pasty, sticky, and devoid of all granulation. In its present hard dry condition it would be saleable in the bazaar at about Rs. 2-8 to Rs. 3 a bazaar maund, but if subjected to a damp atmosphere or kept during the rainy season, it would quite change its character and become dissolved in the form of molasses, in which state it would be suitable for distilling into spirit only, and be worth about Re. 1 to 1-8 a bazaar maund.

"I am however of opinion that with care and cleanliness in boiling the expressed juice and better manipulation generally, this plant is capable of yielding a good marketable *goor*, that further efforts should be made to improve upon the sample now under consideration, and in doing so that details should be given of the cost of producing it, and that a larger sample be furnished.

"The samples of the cane-like stalks after pressing, prepared in the unbleached and bleached state for paper material, are too small, insignificantly so, to admit of a very reliable opinion being given. They would be suitable as short stuff for filling in the 'Pulp,' at a low price, and as such would make fair raw material for paper manufacturing; but the main questions for consideration are—what would be its first cost, then the cost of transport to the consuming market or paper mill, and whether the supply would be constant and to what extent. I submit it would be well in all such references as this one that large samples should be supplied to enable experts to give reliable opinions, and that full details of cost, &c., should be furnished, so that with such data at hand it might be seen if any good practical results would be the outcome of further investigation and trials. The subject is one of much interest and importance in the increasing demand for paper-making materials with which this country abounds."

GARDEN.

The Superintendent of the Garden reports that the tanks now hold a very good supply of water which will be invaluable in the coming dry season, that the labor force is busily employed in clearing all jungle and generally cleaning up the grounds, now that the pruning is nearly finished, and that the general average of germination of imported seeds promises fair, all things considered, but that he hopes to furnish the usual detailed statement in due course.

CACAO.

INCREASE OF CACAO CULTIVATION IN TRINIDAD.

IN the first half of 1882, the exports of cacao had risen to over ten millions of pounds against an average of eight millions, and the *Trinidad Chronicle* states:—

"The laying out of new land in cacao goes on unceasingly, as it has been doing over the last 12 or 14 years, the great majority of the plots, small at first, owned by small people *ci-devant* labourers and contractors, and cultivated by themselves, but by degrees forfeited to the merchants to whom they are indebted for advances, and by amalgamation converted into good-sized properties counting acres by the hundred and (the cacao) trees by the tens of thousands. There is no movement corresponding to this in cane; and the opening of new cane estates on any scale—and a large one, *ab ovo*, is the rarest of *rara avis*—goes on slowly indeed. It cannot be done without capital, a capital of thousands sterling, while a very small purse of savings will give a man courage to buy and lay down, in cacao and provisions, a little plot of ten or twenty acres. Yet it is pleasing to note that where a new line of road cuts through virgin land, as at Conupia, by the railway, buyers start up from the ground as it were that no one dreamt of, men in the town successful in business or trade whom no one had previously credited with a taste for cultivation, yet who, on being tested, have been found to be gifted with a somewhat mechanical capacity for the pursuit quite equal to, and in some respects possibly better, than old clo.-plodders to the manner born, carrying into the new practice the habits of foresight and perseverance that had gained them their first successes and yielded them the means to enter on an untried venture.

"Mr. Fabien's place, *Enterprise Farm*, a piece of 300 acres, lies on the opposite or east side of the railway. He has a mile of frontage on the line, and is about a mile from the railway station. The farm presents, for Trinidad, a very varied scene: Liberian coffee is represented by 5,000 trees, the St. Anna hybrid coffee by 15,000 plants, the Tona-beans tree by 1,000 plants, at present about five feet high, and which are expected to come into bearing in four years from this. Of tobacco, he has 25 acres, managed by Mr. Anderson, who brings Jamaica experience to the task: 5 to 6,000 lb. have been cured, or are now curing, of this crop, and some of it is on sale in town. Mr. Fabien, being apianian as well, has imported some Italian bees, got sunflower seed, hives, and books and journals on the subject, from America; but in this line cannot yet speak of success, finding the *Qu'est ce qu'il dit* even fonder of his bees than himself, and that the latter were attacked also by a certain species of ant. In time, no doubt, he will find a way to neutralize these attacks and get a profit from his bees. He has succeeded in making a *Quezo de mano*,—little hand-made cheeses weighing a pound, cream white like the big Ilano cheeses of Maturin we get from the Spanish Main, but much cleaner. They have the same peculiar sourness and absence of fatty richness, though made from unskimmed milk we are assured, but of a flakey texture that some admire. For these cheeses, Mr. Fabien says, he has a demand for more than he now makes, though he gets half a dollar a pound for them. But his chief object in keeping a stock of milk cows was to supply the town with pure milk, a very laudable idea, to which a great many will wish success. The milk is brought to town by rail, and has a remarkable keeping property. We are not sure we have exhausted the list of experiments—enterprises we should rather call them, with those we have named. Enough has been said, however, to show the new spirit that has been evoked by the opening of the Southern Railway, and the certain extension of settlement that follows the judicious construction of improved communications. Like causes, like conveniences produce like effects here as in Australia or America, though on a smaller scale. If our ruling minds, freed from other care, would direct their thought seriously to the subject, we are persuaded they could attract settlement to the island at a much faster rate than it is now progressing at; and would not every interest in the colony be advantaged thereby? Who can doubt it?"

CINCHONA.

CINCHONA IN MADRAS.

THE Ootacamund correspondent of the *Madras Mail* discusses the prospects of cinchona cultivation in the Presidency :—

That it should rain on the Kartighi feast day is said to be lucky, in native estimation, but we have had just a little too much of it this year, and our 'growers' complain that their tea, coffee, and cinchona are coming to grief. Cinchona, of course, suffers least, it is so adaptable a creature, willing to flourish in almost any ground and at almost any altitude, from 7,500 feet down to 3,000, if but due regard be had to its varieties. Crown bark (*Condiminia*) may be seen growing far up towards the crests of the Doddabetta range; red bark (*Succirubra*) succeeds best at 5,000 feet; yellow bark (*Calisaya*), and the more delicate hybrids (*Llanosa*, *Pubescens*, &c.), and also the recent varieties imported lately from Java, are, as distinguished strangers, accustomed to greater care being shown in their raising and bringing up, and a lower elevation to live in. They flourish well in an altitude of 5,000 to 3,500 feet, and repay their grower for the extra anxiety bestowed upon their education by a large yield of quinine. It may be said broadly that when the soil is good and frosts not severe, cinchona may be cultivated successfully from the crests of the hill-tops to the semi-tropical plateaux of Wynnad. A ride from Ootacamund *via* the Government plantation at Neddiwuttam, down the Guddalur ghat, and so on to Devalah and Cherimbady, on the borders of S. E. Wynnad, would not only convince the most sceptical of the advantages of cinchona growing, but also prove a source of pure delight, from its constant change of lovely scenery, flora, fauna, and ever-hospitable planters. Local causes, of course, affect the growth of the best intentioned cinchona; the aspect, soil, and elevation may seem favourable, yet a wind round an unsuspected corner, a want of cover, or an access of frost, may destroy the best laid plantations. The unfortunate victims cannot explain their sufferings, so they die to allow their owners to learn by experience. It is interesting at the Government plantations at Neddiwuttam, at Deva Shola, and other places where crown and red barks grow side by side, to notice the points where one deteriorates and the other improves, the deterioration and improvement following upon elevation, prevailing winds, and other climatic causes. Cinchona growing is certainly our most paying industry, and unless some wonderfully effective febrifuge be shortly discovered, even those who now begin to plant ought to make a fortune from this tree of knowledge. The quantity of bark now going to market must in some measure affect prices, but allowing for a fall of 50 per cent within the next ten years (which is scarcely likely to occur), still an ample margin of profit would be left to any one with sufficient capital to pay out, and not expect to bring in for six years. The want of capital is the root of all evil in all our hill industries. Cinchona, gold, tea, and coffee alike, suffer from want of funds; men believe they can make their fortunes by laying hold of the rope, and forget that they must go on pulling. And things are not quite evenly balanced too: the moneyed men probably have no application, the persevering men no money. But to cease moralizing and give some statistics will best please your readers, and I can speak from most reliable data. Roughly speaking, to purchase and bring under cultivation one hundred acres of cinchona would cost from one lakh to a lakh and quarter of rupees to the end of the sixth year; the removal of bark can commence in the fifth year, and extensive barking during the sixth. All expenses, including interest at six per cent on outlay, should ordinarily have been paid, and half a lakh profit or more remain in addition. At the end of the sixth year of famine, comes the plenty following the famine, the lean planter will now become the fat planter, for he will have an estate to show worth from ten to twelve thousand pounds, and his five thousand pounds gained by sale of bark wherewith to enlarge his border. Is it surprising that I place cinchona foremost among mountain money-making?—*Madras Mail*.

CINCHONA SALES.—The change made in the conditions of sale of East India Bark, under which the deductions for draft, tret, dust, and discount were abolished, and payment to be made upon the net re-weight, came into operation at the periodical auction on Tuesday, the 7th Nov., and producers are to be congratulated upon the result so far. The old allowances amounted to fully 10 per cent, and it was only natural to expect that buyers

would make something like this difference in their bids, but such was not the case. It is the unanimous testimony of selling brokers that the prices paid on this occasion were quite as high, and in some instances even higher, than at the previous sale, when the former conditions were in force, so that, practically, importers realised an advance of fully 10 per cent, and yet the market for cinchona bark generally is by no means animated just now, as quinine has fallen to 8s. 6d., and stocks show a tendency to accumulate. No one will be surprised to hear that the importers of South American Bark have demanded that the new conditions of sale shall be extended to it, and this has been conceded by the trade.

CINCHONA SOILS.—Mr. John Hughes, F.C.S., has lately subjected to analysis a number of samples of soil from the Government Cinchona Plantations on the Neilgherry Hills, and he is preparing for the press a paper on the subject. He is of opinion that the wide range of quality in bark of the same species is mainly due to the difference of soil; that is to say, to the presence or absence in its composition of the nitrates and carbon which form the food of the plant, and go to produce the alkaloids in its bark. Hitherto, scarcely anything has been known as to the chemical composition of soil best suited to the growth of cinchona; for even Mr. Clements Markham, who is recognised as the authority on the habits of the plant, only tells us that in its own home, he found it growing in forest land—which is decidedly vague and unscientific. The result of Mr. Hughes' researches will therefore be most opportune and valuable, and may be the means of preventing much useless outlay of time and money in planting cinchona on unsuitable soil.

FORESTRY.

ROOT AND BRANCH.—I had a fancy some years ago that something might be done in the forestry of conifers by restricting growth to the terminal bud alone. For this end all the side buds of some Scotch firs were removed yearly as soon as they were well developed. My largest specimen is now a finely grown tree some 40 feet high. For eleven years successively it was operated upon as I have described—in fact, as long as I could get the leading shoot without the aid of a ladder. When this tree is put into the saw-pit it should, barring accidents, afford 11 foot boards of utterly faultless timber. Of course, if the laterals had been allowed to grow the plant would have been weight for weight larger at the end of the eleven years, but I think that in some fifty or sixty years hence the difference will be found inappreciable.—*R. Trevor Clarke*.

THE GARDEN.

NOTES from the Gardeners' Chronicle.—**TOMATOS.**—Tomatoes should be grown in a light soil not too highly manured, as the plants will otherwise go too much to top, and they do not fruit until they have made a certain amount of growth, and have become well established. Another point is that when tomatoes are grown in the open air trained to stakes, a yard in height will be found sufficiently tall for the plants to develop and mature their fruit, and while it is necessary to disbud freely and thin out the laterals, the tops of the plants should not be moved until the crop of fruit is set, and when this has happened, the plants need to be thoroughly thinned that sun and air may be admitted to assist in the ripening of the fruit.

A very large amount of tomato seed is required for sale: a great deal is obtained from America, but very large quantities of tomatoes are grown in Italy to supply seeds for this country. The crop, it is thought, will this season be comparatively light owing to the prevalence of floods in the tomato-growing districts, which have destroyed many of the plants. A great quantity of tomato seed is sent to India, not so much in varieties as in mixtures of all sorts. Indian growers appear to give preference to a variety of sorts over individual quality.—*R. D.*

TOMATOES AS PICKLES.—Any one having any ripe fruits of tomatoes will find they make a delicious pickle by merely placing them in a jar, covering with the best vinegar, and tying down securely for a fortnight; the addition of two or three capsaicums improves them in some people's opinion; others prefer them cut open when fit for use, and a little of Lea and Perrin's Worcester sauce added. The small kinds, ranging in size from that of marbles to walnuts, are the best for the purpose. The small green fruits are also much relished by some, but they require to remain longer in the vinegar before using.—*W. H. Divers, Burghley.*

THE STORING OF TREE LEAVES.—There can be no doubt but that decayed vegetable matter, which may be considered the most natural fertiliser provided for plants in a wild state, is also the best fertiliser we can provide for them in what may be called an artificial state, where, whatever help they would get under natural conditions, through the natural decay of *debris*, we, through the operations on which a high state of keeping depends, deprive them of a chance of assimilating, and it thus becomes imperative to provide the best substitute we can. As the trees are now commencing to shed their leaves in earnest, those which were stored last year should be at once turned over into the place previously occupied by that which has been shifted to the soil-ground in readiness for use, and the space (which should be ample) filled with a fresh supply as they are accumulated. To carry out this matter a large space should be set apart in a sheltered out-of-the-way corner, one-half of which should be filled with fresh leaves every year, to be turned over to undergo another year's decomposition, after which it will be sufficiently friable for use.

CHARRED RUBBISH.—Another very useful fertiliser is formed from the *debris* collected during the season from lawns, flower-beds, and borders. Wherever there is a practicability of subjecting the whole of it to the action of fire from time to time, and thrown into a heap, it becomes a valuable material for renovating exhausted beds and borders.

DECOMPOSED MANURES.—It is oftentimes necessary to apply more stimulating material than the above, for which a due provision should be made. Thoroughly decayed manure from the cow-yard will be found the best stimulant to apply to hot and dry soils, but well-fed horse-manure is best suited to the generality of soils, and for the purposes of the flower garden there should be an ample store put by every year. It should be frequently turned over for aeration and decomposition, as it is best for use after at least two years' submission to the action of the atmosphere.

LOAM.—This material is such an obvious necessity in the flower garden, that I scarcely need remind the operator to take advantage of any leisure opportunity to secure a good supply. I prefer a good loam from off the chalk.—*John Cox, Redleaf.*

SERICULTURE.

AT the exhibition of silk cocoons held at Modhopore in the month of May, the number of exhibitors was 720 as compared with 447 last year. There was a large increase both of agriculturist and non-agriculturist exhibitors, and, but for disease among the worms which has now spread to the foreign stock, the prospects of the new industry would be very bright. Last year only silkworm-rearers from Gurdaspore and Kangra were present, but this year a few came also from Sealkote, Umritsur, and Hoshiarpore. The report submitted to the Government goes on to say:—

The result of the prevalence of disease among the silkworms has been a greatly diminished outturn in the cocoons. The falling off has been so serious that Messrs. Lister and Co. have had to obtain some part of the requirements of their filature from Bengal, and the Commissioner of Umritsur fears that, unless prompt measures are taken to replace the diseased by healthy stock, sericulture in his division will suffer "irreparable injury." The main original cause of the disease in Kangra and Gurdaspore is probably the uncleanness of the huts in which the worms are reared, and apparently when disease has

once begun in a rearing shed, it spreads by contagion. It appears from a recent article in the *Indian Agriculturist* that more than once silkworm-rearers in Italy have lost the whole of their stock from disease, and have had to depend for fresh rearing on ova imported from other countries. The Financial Commissioner agrees with Colonel McMahon in considering that there is serious risk of the extinction of a very promising industry. He thinks, therefore, that the Commissioner of Umritsur should be asked to submit, after consultation with the agents of Messrs. Lister and Co., a special report as to the measures he deems necessary, and as to the cost which the destruction of the diseased, and the supply of healthy, seed would involve. At present we are quite in the dark on the latter point. Messrs. Lister and Co. might, in their own interests, bear a considerable part of the expense, and the rest might be met by the district committees, aided, if necessary, by help from Government. The Financial Commissioner has called for a special report on the feasibility of the plan of bringing up and destroying all diseased worms. The extract from the Annual Revenue Report of Kangra, given below, will show that a good deal is being done in that district to encourage sericulture. It would be a good thing if some of the tea-planters in the Kangra Valley would take up the industry, for their example might teach the natives better methods. Sericulture is likely to make great strides in this district if it is properly fostered. A separate report has been sent to the Commissioner in connection with this subject, and the Madhopore fair. I need say nothing more now, except that the amalgamation of the Nurpore and Gurdaspore fairs at Madhopore was a most unlucky step, and that to insure any success in sericulture in Kangra, the fair must again be made local. Rearing sheds on proper principles must be built, if the worms are to be protected from suffocation and death. These should in the first place be built by the district and municipal committees. People should be taught to manage their worms on a proper principle, and should be taught the simple problem that, if x is the selling price of any article, the man who can produce it for $x-1$ anna is making a profit, while he who produces it for $x+1$ anna will in the end be ruined. It is only a difference of 2 annas, but it is the difference between prosperity and ruin. It is a difference caused by one sericulturist working on scientific principles and another by rule of thumb. Mulberries of the China and Philippine variety should be planted in large quantities, nor should planting of country mulberries be neglected.

We have hitherto been playing with sericulture, but if we now exert ourselves there is no reason why it should not in time rival tea in its capacity for bringing wealth into the district. If we had only four or five acres of tea in the district turning out 1,000 lb. of tea, the result would be inappreciable. Now that we turn out a few maunds of cocoons annually, the result is also inappreciable. If we turned out several thousands annually, and there would be no difficulty in this, we might consider that a fresh source of wealth was open to the people. In sericulture I consider we have as yet done nothing; we might do a great deal.

TEA.

THE RETAIL PRICES OF TEA.

SOME correspondence has been going on in the daily papers on this subject, and suggestions more or less practical have been made. It is insisted on that the grower literally outlays his capital to enable the retailer to make enormous profits.

We have before us the price list of a so-called "Agency," which has been recently opened (and which affects to introduce the quite new element of cheapness), where the following rates are quoted for,—

| | | | Rs. A. P. |
|-------------------------------|-----|-----|-----------|
| Choice Flowery Pekoe, per lb. | ... | ... | 4 0 0 |
| Flowery do. | ... | ... | 3 0 0 |
| Orange do. | ... | ... | 2 0 0 |
| Pekoe do. | ... | ... | 1 4 0 |

These prices are, it is true, below the ruling retail rates, but even supposing the teas to be what they are represented, the margin of profit on auction cost would be at least 100 per cent.

We suppose the public would not be fools enough to pay high prices if they knew where to get low ones; and surely it is worth the while of owners to assist them to this end. The bulk of the Kangra and Kumaon teas are consumed in the district, and very largely through direct retail orders—that is, parties send to the gardens for parcels of 2lbs. and 5lbs. at a time, and teas so ordered are sent free by post. Why could not the same thing be done between owners' representatives in Calcutta and the residents of the lower part of Bengal? For distant places one or two agents might be appointed to supply circles otherwise too far separated. Then there are the railway refreshment-rooms throughout India, where special brands on a moderate commission might be the guarantee of stated qualities given by owners, together with the reduction of present retail rates which would be feasible, could not but attract the public, who would desert the present retail shops and bazaars, to their own considerable advantage, and to the profit of owners. The cheapness of the tea, further, might attract the middle class of natives, especially if their convenience was consulted by packets offered of sufficiently small weight. A certain amount of capital would necessarily have to remain locked up, but where there are so many public Tea Companies as are found represented in Calcutta, the strain upon each would be slight indeed. To induce tea drinking among the natives must manifestly be a work of some time, but we do not see why it should not gradually take place: only in this case native agency must be resorted to. Surely one trustworthy shop-keeper could be found in each prin-

cipal native town who would be glad to exert himself for a liberal commission. To arrange this portion of the business a native traveller would have to be employed; but this would not cost much.

Of course combination, primarily, among the representatives of tea owners and companies would be necessary,—somewhat in the way of a syndicate; but there should be no difficulty about this. One paid assistant could do all the actual work. The teas contributed could, if desired, be bulked under the Syndicate's mark, and payment could be made for them in the ratio of quantities supplied.

There seems no reason no doubt that nearly the whole of the existing retail trade could be diverted from shop-keepers to owners, which latter would receive, even at sale prices greatly below those at present charged, double the rate they now get. True, the consumption of tea in this country is not gigantic, but it is several million pounds yearly, and China supplies, alone, 5 millions, which by proper organized effort on our parts, ought not to be the case.

The scheme we roughly indicate could of course be carried out by an individual or private company with sufficient means, but the desideratum of low prices to the public (yet handsome return to the owners) would not then be obtained. It may not matter to Mr. Tomkins, C.S., what price he pays for the tea he drinks (though it ought to matter to him whether he gets what quality he pays for); but there are a good many of the subordinate European and Eurasian class to whom price matters a good deal, and who perhaps have to go without the wholesome beverage because they cannot afford to pay the absurd prices now asked for it.—*Indian Tea Gazette.*

ZULULAND AND CETEWAYO.

"I know what it is," he answered; "this honey is made from euphorbia flowers, which are very poisonous." This explanation made me feel exceedingly uncomfortable; but I elicited from him that there was not much danger, as the 'maasa' taken with it would neutralise the effect of the poison. Directly he mentioned poison I dived into the packs, and pulled out a bottle of ENO'S FRUIT SALT, and emptying a quantity into two panikins, filled them up with water, and several times repeating the dose, in a few hours we were considerably better."—*"Zululand and Cetewayo," (p. 139), by Captain W. R. Ludlow, 1st Batt. R. F. Royal Warwickshire Regiment.*

"What on earth shall I take to Zululand?" asked my friend Jim Law one day at Aldershot, when he had just received orders for South Africa, to start at forty-eight hours' notice. I replied, 'If you take my advice—and it's that of an old traveller—you'll not budge without a few bottles of ENO, even if you leave half your kit behind. I never am without these Salts, and, please the pigs, never intend to be.' On his return I inquired, 'Well, how about ENO'S FRUIT SALT?' 'My dear fellow, it was the best advice you ever gave; they saved me many an illness; and when I left Tugla, I sold the remaining bottles for ten times the original price!'—*Lieut.-Col.*

JEOPARDY OF LIFE. THE GREAT DANGER OF DELAY.

You can change the trickling stream, but not the raging torrent.

WHAT EVERYBODY SHOULD READ.—How important it is to every individual to have at hand some simple, effective, and palatable remedy, such as ENO'S FRUIT SALT, to check disease at the outset! For this is the time. With very little trouble you can change the course of the trickling mountain stream, but not the rolling river. It will defy all your tiny efforts. I feel I cannot sufficiently impress this important information upon all Household, or Ship Captains, or Europeans generally, who are visiting or residing in any hot or foreign climate. Whenever a change is contemplated, likely to disturb the condition of health, let ENO'S FRUIT SALT be your companion; for, under any circumstances, its use is beneficial and never can do harm. When you feel out of sorts, yet unable to say why, frequently without any warning you are suddenly seized with lassitude, disinclination for bodily or mental exertion, loss of appetite, sickness, pain in the forehead, dull aching of back and limbs, coldness of the surface, and often shivering, &c., &c.; then your whole body is out of order, the spirit of danger has been kindled, but you do not know where it may end: it is a real necessity to have a simple remedy at hand that will answer the very best end, with a positive assurance of doing good in every case and in no case any harm. The pilot can so steer and direct as to bring the ship into safety, but he cannot quell the raging storm. The common idea when not feeling well is, "I will wait and see, perhaps I shall be better to-morrow;" whereas, had a supply of ENO'S FRUIT SALT been at hand, and use made of it at the onset, all calamitous results might have been avoided. What dashes to the earth so many hopes, breaks so many sweet alliances, blasts so many auspicious enterprises, as untimely death?

ENO'S FRUIT SALT.—"After suffering for nearly two and a half years from severe headache and disordered stomach, and after trying almost everything and spending much money without finding any benefit, I was recommended by a friend to try ENO'S FRUIT SALT, and before I had finished one bottle I found it doing me a great deal of good, and now I am restored to my usual health; and others I know that have tried it have not enjoyed such good health for years.—Yours most truly, ROBT. HUMPHREYS, Post Office, Barrasford."

SUCCESS IN LIFE.—"A new invention is brought before the public, and commands success. A score of abominable imitations are immediately introduced by the unscrupulous who, in copying the original closely enough to deceive the public, and yet not so exactly as to infringe upon legal rights, exercise an ingenuity that, employed in an original channel, could not fail to secure reputation and profit."—*ADAMS.*

CAUTION.—"Legal rights are protected in every civilized country. Examine each Bottle, and see the capsule is marked 'ENO'S FRUIT SALT.' Without it you have been imposed on by worthless imitations. Sold by all Chemists, price 2s. 9d. and 4s. 6d."

DIRECTIONS IN SIXTEEN LANGUAGES HOW TO PREVENT DISEASE.

Prepared only at ENO'S FRUIT SALT WORKS, HATCHAM, LONDON, S.E., by J. C. ENO'S Patent.

THE GREAT REMEDY FOR PRICKLY HEAT, INDIGESTION, HEADACHE, BILIOUSNESS, AND FEVERS.

The testimony of medical gentlemen has been unqualified in praise of

LAMPLOUGH'S PYRETIC SALINE,

As possessing elements most essential for the restoration and maintenance of health with perfect vigour of body and mind.
It is Effervescent and Tasteless; forming a most invigorating, Vitalising, and Refreshing Beverage.
Gives instant relief in HEADACHE, RHEA or BILIOUSNESS, CONSTIPATION, INDIGESTION, LASSITUDE, HEARTBURN, and FEVERISH COLIC; prevents and quickly cures the worst forms of TYPHUS, SCARLET, JUNGLE, and other FEVERS, SMALLPOX, MEASLES, and ERUPTIVE or SKIN COMPLAINTS, and various other altered conditions of the blood.

Dr. FROST—"Unfolding source of immense benefit to mankind."
Dr. MORRIS—"Is furnished the blood with its lost saline constituents."
Dr. SPEAKS (Government Medical Inspector of Emigrants from the Port of London) writes—"I have great pleasure in bearing my cordial testimony to its efficacy."

GOVERNMENT OFFICIALS AND PLANTERS caring for the welfare of their employes should note its value as a specific in Fever cases.

Dr. J. W. DOWLING—"I used it in the treatment of forty-two cases of Yellow Fever, and am happy to state I never lost a single case."
Dr. W. B. DUFFY—"Since its introduction the Fatal West India Fevers are deprived of their terrors."

THE HONORABLE REPRESENTATIVE OF THE GOVERNOR OF SIERRA LEONE, in a letter of request for an additional supply of the Pyretic Saline, states—"It is of great value, and I shall rejoice to bear it to the houses of all Europeans visiting the tropics."

To be obtained of any Chemist or Drug Store, in Patent Glass-stoppered Bottles, 2s. 6d., 4s. 6d., 11s., and 21s. each.
Please note in connection with the recently observed effects of the use of Citrate and other preparations of Magnesia that LAMPLOUGH'S PYRETIC SALINE is warranted not to contain any substance which would cause calculous or other earthy deposits.

H. LAMPLOUGH, 113, HOLBORN HILL, LONDON, E.C.

GOVERNMENT CINCHONA FEBRIFUGE.

Afficient substitute for Quinine. Sold by the principal European and Native Druggists of Calcutta. Obtainable from the Superintendent, Botanical Gardens, Calcutta. Post free, at 4 oz., Rs. 6; 8oz., Rs. 11; 16 oz., Rs. 20-12. Cash with order.

NOTICE

TO MANUFACTURERS,

AND

OTHER USERS OF POWER IN BULK.

WATER POWER, varying from 100 to 1,000 H.P., is available at 38 sites on the Bari Doab and Western Jumna Canals in the Punjab.

The tracts in which the Water Power is situated are—

(a) Between the rivers Beas and Ravi, to the north of the Schude, Punjab and Delhi Railway, 26 sites, close to the Umritsar and Pathankote Railway now under construction.

(b) To the west of, and about 16 miles from the river Jumna, 12 sites, on a navigable canal running from Kurnal to Delhi, and within easy distance of the Grand Trunk Road.

Lease will be granted for 20 years, on the following approximate rates per H.P. per annum:—

| | | | | | |
|---------------|----------|-----|-----|-----|------|
| For the first | 3 years | ... | ... | Rs. | NIL. |
| " " | second 5 | " | ... | " | 60 |
| " " | third 6 | " | ... | " | 100 |
| " " | fourth 6 | " | ... | " | 150 |

Full particulars can be obtained from the Office of the Joint-Secretary to Government, Punjab, Irrigation Branch, Lahore, and information, regarding the Water Power available at the various sites and their local advantages, can be obtained from the offices of the Superintending Engineer, Bari Doab Canal, Umritsar, and Superintending Engineer, Western Jumna Canal, Delhi.

By order,

R. HOME, LT.-COL., R.E.,

Off. Joint Secy., Govt., Punjab,

P. W. D., Irrigation Branch,

Lahore, January 24, 1882.

PHOENIX IRON WORKS, CALCUTTA.

THE OLDEST ENGINEERING ESTABLISHMENT IN INDIA, JESSOP & CO.,

**Civil and Mechanical Engineers, Contractors, Brass and Iron Founders,
Metal Merchants, &c.**

*Forged and Cast Iron Work, Boilers, Machinery for Jute, Cotton and Rice Mills, Collieries, Indigo Concerns, Tea Gardens, &c.,
Contractors' and Brick-making Plant, and every class of Iron and Brass Work made to order.*

SOLE AGENTS FOR

Robey & Co's celebrated Portable and Fixed Engines and Machinery, Gwynne & Co's "Invincible" Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

IMPORTERS AND MANUFACTURERS OF EVERY DESCRIPTION OF STEAM ENGINES AND MACHINERY.

Robey & Co's Portable, Horizontal, Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand, Lift and Force Pumps, Tangye's "Special" Steam Pumps, "Vauxhall" Donkey Pumps, Flour Mills, Soorkee Mills, Png Mills, Brick-making Machines, Road Rollers, Saw Benches, Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines, Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selkirk's Boiler Tube Benders, Steam Pressure Recorders, Electric Pans, Richard's Engine Indicator, Gifford's Injectors, Cooking Stoves, Fire-Proof Safes.

The following are the principal advantages of the "Invincible" Pump:—

1st.—It is arranged to swivel on the bed plate, and may be placed at any angle simply by slackening a few nuts, without interfering in any way with the bed plate or the joints of either the suction or discharge pipes.

2nd.—It does not require a foot valve, being fitted with small air exhauster and clack on discharge which always keep the pump charged ready for work.

3rd.—The bearings are made on an entirely new principle, and one bearing will last out four of the old arrangements.

**J. & H. GWYNNE'S
"Invincible" Centrifugal Pump.**

4th.—The form of the pump casing is so arranged that one side can be taken off in a few minutes for the inspection of the whole of the disc and interior of the pump.

5th.—Hand holes are made on each side of the suction pipes to enable any foreign matter which may get into the pump or disc to be easily removed. The covers are fitted with a bayonet joint so that they can be removed and replaced in less than a minute.

6th.—The "Invincible" is 25 per cent. lighter than any other Centrifugal Pump in the market, and discharges at least 10 per cent. more water for the power applied.

Ransome's Indian Plough. Price, Rs. 15.

Howard's Ryots' Plough. Price, Rs. 20.

These Ploughs have been expressly designed and manufactured for the use of the Ryots of India, whose special needs have been carefully studied in their construction. They embody all the qualifications for which the native-made implements have hitherto been preferred, whilst being incomparably superior in strength, durability, and efficiency.

MORAE'S PATENT SUB-SOIL AND GENERAL PLOUGH

Stirs up the soil to three times the depth of a native plough, and leaves the good mould on the top. Goes through the dirtiest land without getting choked with weeds. Price, Rs. 15.

INDIGO AND TEA PLANTERS' IMPLEMENTS AND STORES.

ENGINEERS' TOOLS AND STORES OF ALL KINDS.

ALWAYS ON HAND A LARGE STOCK OF PLATE, BAR, ANGLE, TEE AND CORRUGATED IRON, STEEL, BRASS, COPPER, PIG IRON, FOUNDRY COKE, SMITHY COAL, FIRE BRICKS, AND FIRE CLAY.

 Catalogues on Application.

GOODALL'S Household Specialities.

A Single Trial solicited from those who have not yet tried these Splendid Preparations.

YORKSHIRE RELISH.

The Most Delicious Sauce in the World.

This cheap and excellent Sauce makes the plainest viands palatable, and the daintiest dishes more delicious. With Chops, Steaks, Fish, &c., it is incomparable. In bottles, at 6d., 1s., and 2s. each.

GOODALL'S BAKING POWDER.

The Best in the World.

Makes delicious pudding without eggs, pastry without butter, and beautiful light bread without yeast. In 1d. packets, 6d., 1s., 2s., and 5s. tins.

GOODALL'S QUININE WINE.

The Best and most Agreeable Tonic yet introduced.

The best remedy known for Indigestion, Loss of Appetite, General Debility, &c. Restores delicate individuals to health. At 1s. 1d. and 2s. 3d. each bottle.

IN EVERY PART of the WORLD,

INCLUDING—

The Proprietors, *Indian Agriculturist*, Chowringhee-road, Calcutta; the Great Eastern Hotel, Company, Limited, Calcutta; Messrs. Wilson, Mackenzie & Co., 13, Old Court House-street, and 1, Mangoe-lane, Calcutta. Orders received by Messrs. King, Hamilton & Co., Calcutta.

NOTICE.

In ordering through London Shippers, purchasers should be particular to stipulate for **SUTTON'S SEEDS.**

TESTIMONIAL.

From S. Jennings, Esq., late Vice-President of the Agri-Horti Society of India.

"With reference to your mode of packing seeds for export, I must say how much I was gratified with the system you were so good as to show me. During the whole of my long Indian experience, it was my constant regret that English packed seeds were almost invariably lower in germinating power than the American. After seeing the elaborate precautions you take in executing such orders as that of the Agri-Horti Society of India, I am by no means surprised to hear that you have been gratified by the receipt of so much testimony from the tropics as to the condition of your Seeds upon arrival."

Sutton Sons

THE QUEEN'S SEEDSMEN,

New York, 1880. Berlin, 1879. Melbourne, 1880. Hamburg, 1878. Cincinnati, June, 1880.

OVER 450,000 FEET SOLD DURING 1881,

Including 3,877 feet of main Driving Belts, of widths ranging from 13 in. to 60 in., are working in over 6,000 Mills and Works in Europe and America.

The following Tests (by Kirkaldy, of London) show the relative strength and value, compared with Leather.

| | Breaking Strain per Square Inch of Section. | Price per foot. |
|-----------------------------------|---|-----------------|
| Best Double Leather 6 in. Belting | 3,972 lbs. | 5s. 7d. |
| Gandy's 6 in. x 6-ply Cotton | 6,811 lbs. | 2s. 6d. |

THE
GANDY BELT.

Any Length or Width
for Main Driving.

It is the best belt ever made for all purposes. Much cheaper and stronger than leather. Thoroughly waterproof, and not affected by temperature, clings well to the pulleys, runs true, and can be made any length without joints. This Series of Belting (see engraving) was supplied in One Order to Messrs John Crossley and Sons, Halifax, May 1, 1880, and continues to give entire satisfaction.

THE "GANDY" BELT.
GANDY'S Patent American Cotton Belting can claim a superiority over leather belts in every particular, its cost being about half that of leather, while its strength and gripping power is about double that of the best leather, as shown by repeated tests taken by Kirkaldy, of London. These tests are given above, to which special attention is directed. These "Gandy" belts are made of any width up to 72 inches, and any length up to 340 feet without joint, thus obviating the necessity of having two belts on the same pulley, a system of driving which is never satisfactory, as it is impossible to have belts of exactly the same tension; hence one or the other is always causing a stoppage. These stoppages are avoided by using Gandy's Patent Belts in one width. These Gandy Belts are made of the finest American Cotton Duck, specially prepared at Baltimore for the purpose, and then put together and finished by Gandy's patented special Machinery and process to prevent stretching, and render them impervious to atmospheric influence. Possessed of advantages such as these, the universal adoption of Gandy's Belts can only be a question of time.

A SUBSTANTIAL GUARANTEE GIVEN WITH EVERY MAIN DRIVING BELT.

MAURICE GANDY, Patentee and Manufacturer, LONDON. WORKS: Liverpool, England; and Baltimore. U.S.A.

DR. LALOR'S PHOSPHODYNE.

(Trade Mark—Phosphodyne.)

TWENTY YEARS' PUBLIC TEST, AND THOUSANDS OF TESTIMONIALS FROM

ALL PARTS OF THE WORLD ESTABLISH

PHOSPHODYNE

as the only Safe, Reliable, and Never-failing Phosphoric Remedy for Over-worked Brain, Sleeplessness, Harassing Dreams, Worry, Anxiety, Excitement, Epilepsy, Business Pressure, Wasting Diseases, Nervous Prostration, Stomach and Liver Complaints, Impoverished Blood, Premature Decay, and all morbid conditions of the system dependent upon the deficiency of the Vital Forces.

DR. LALOR'S PHOSPHODYNE PURIFIED AND

Enriches the Blood, Clears the Skin, thoroughly Invigorates the Brain, Nerves and Muscles, Re-energises the Failing Functions of Life by supplying the PHOSPHORIC element which has been wasted, and thus imparts Energy and Fresh Vitality to the Exhausted Nervo-Electric Force, and rapidly Cures every form of Nervous Debility, Paralysis, Kidney, Nervous, Mind, and Heart Diseases, from whatever cause.

This elegant Phosphatic combination, the Wonder of Modern Chemistry, is pronounced by the most eminent members of the Medical Profession to be unequalled for its power in replenishing and elaborating the Vitality of the Body; by its supplying all the essential and vitalising constituents of the BLOOD, BRAIN, and NERVE SUBSTANCE; and for developing all the Powers and Functions of the System to the highest degree; by its being agreeable to the palate, and innocent in its action. While retaining its wonderful properties, it acts as a Specific, surpassing all the known THERAPEUTIC AGENTS of the PRESENT AGE, for the SPEEDY and PERMANENT CURE of the above diseases.

DR. LALOR'S PHOSPHODYNE is sold in Bottles at 4s. 6d. and 11s. by all Export, Wholesale, and Retail Medicine Vendors throughout the World.

IMPORTANT NOTICE.—NONE IS GENUINE UNLESS the name, Dr. Lalor's Phosphodyne, London, England, is blown in the Glass of each Bottle, and every Bottle bears the British Government Stamp, with the words DR. LALOR'S PHOSPHODYNE, London, England, engraved thereon by Order of her Majesty's Honourable Commissioners; IF NOT, IT IS A FORGERY, AND YOU HAVE BEEN IMPOSED UPON BY A WORTHLESS IMITATION.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parentheses, or in a foot-note. The bigah in particular varies so much in the different provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

BOOKS ON AGRICULTURAL CHEMISTRY.

TO THE EDITOR.

SIR,—Will you kindly tell me whose is the best book on agricultural analytical chemistry, where can it be had, and for what price?

RASIK BEHARI BISWAS.

Bissanpore, Bankoora, January 18, 1883.

NOTE.—Johnston and Cameron's *Chemistry and Geology*, 6s. 6d.; Blackwood, 1872.

Sibson's *Agricultural Chemistry*, with Preface, by Voelcker, 2s. 6d.; Routledge, 1867.

Anderson's *Elements of Agricultural Chemistry*, 6s. 6d.; Longmans, 1860.

Church's *Laboratory Guide*, specially arranged for Agricultural Students.

John Van Voorst.

How Plants Grow.

The third and fifth are out of print.

Macmillan has also published a few short text-books, but so far as we know there is no special book on Agricultural Analytical Chemistry.—Ed., J. A.

DIVI-DIVI.

TO THE EDITOR.

SIR,—Some seven months ago, the *Statesman* published a few observations—reproduced in the *Indian Agriculturist* of the 1st July last—regarding *Divi-divi*. Seedlings were recommended to be planted 16 feet apart each way, giving therefore 170 trees to an acre. After seven years an average production of 4 tons per acre of a probable net value of Rs. 350 was confidently promised, and even an outturn of 10 tons was likely not to be uncommon.

As previously to the appearance of those observations, I had seen instructions from a very high authority, directing that *Divi-divi* trees be planted 6 feet apart each way, so as to give 1,210 trees to an acre, which themselves would probably yield from 1 to 3 tons, I cut out the observations in the *Statesman*, and sent them, through an official channel, to the gentleman who had issued the instructions just mentioned. He courteously answered as follows:—

"Without better certified information in connection with the plantations to which the *Statesman* article refers, it would be useless attempting to reconcile the discrepancies between this and the notes I sent to you. They are, as you observe, very considerable, but the article conflicts even more severely with many natural facts, from which it appears certain that the writer has not had the advantage of a practical acquaintance with the subject.

"Taking the article as it comes, we see that the writer in the first place finds fault with the 'Madras contemporary' for speaking of the *Tamarind* and *Divi-divi* as being somewhat like each other. He says they bear no resemblance whatever 'except in the form of the leaf,' but that the *Divi-divi* and the common babool are barely distinguishable.

"In all this the Madras author is right, and his critic wrong. From the sample of *Divi-divi* sent under separate cover you will see that tamarind is not at all unlike it, while the above prints show the leaves to be altogether dissimilar.

"The *Divi-divi* leaf is large and *unequally bipinnate*, while that of the tamarind is only *pinnate* or once divided. The babool, like the *Divi-divi*, has a *bipinnate* leaf, but is *equally or abruptly* pinnated, the leaflets having very little blade. The three trees under comparison are no more like each other in general appearance than are most other members of the same family and tribe, and could never be confounded on careful examination.

"The article states that cattle do not eat the *Divi-divi*; but, as a fact, they are particularly fond of it, as also are sheep, and I notice that my shepherds systematically carry all the suckers and other prunings into the folds as fodder for the flocks.

"The tree is described as very small when young, but under cultivation it grows into a fine big tree. One in the Collector's garden at Dharwar measures about 4 feet round the trunk and covers a considerable area.

"Having had a good deal to do with the propagation and distribution of this plant, I think it is certain I should have heard before of the extensive and systematically worked plantations spoken of in this article had they existed, and if 'ten tons is not an uncommon output' the article necessarily occupies a position either in the export or local market, which is not the case so far as I am aware.

"On the whole I am inclined to believe that the writer is confusing the *Divi-divi* with some other kind of tree. If, however, his facts are as genuine as they pretend to be, his statements are entitled to much respect; for my own part I should hesitate quoting such figures as an inducement to planters; much mischief and disappointment is continually being caused in connection with almost every new industry by the rash representations of enthusiasts that it becomes a duty of experimental institutions in summing up the results of tentative trials, to under rather than over-estimate wherever actual ones cannot be obtained."

Divi-divi plants being naturally semi-procumbent for a number of years, the same high authority recommended that they should be planted in *threes*, to admit of their being plaited together to form one suitable trunk. 1,210 groups of 3 plants each would therefore give 3,630 trees to an acre. Supposing that grouping served only to keep trees straight, and that the yield of a group ultimately be not more than that of a fully grown isolated tree, still, the observation in the *Statesman* really referred to *Divi-divi*. The exact number of seedlings to be planted on an acre remains unsettled. A distance of 8 feet each way between them seems hardly sufficient for trees said to attain a height of 30 feet and a trunk diameter of about 18 inches. On the other hand, if 3 tons be a probable average yield per acre, it looks easier for 1,210 trees than for 170 to give 6,720 lb weight of dry pods. With the first number, the yield of each tree would require to be 5½ lb only; with the second, as much as 39½.

Which is it? The question is an important one. A very few who had embarked in such a kind of cultivation, and found out after seven years they had gone the wrong way to it, would be able to begin again.

BRITISH BURMAH.

NOTE.—It is perhaps best to say frankly that the paragraph about the *Divi-divi* was written (or passed for publication) by the then Editor of the *Indian Agriculturist*, since deceased, and the present Editor is not prepared to settle the points in dispute. The subject is of some importance, and any contribution to our knowledge of it, addressed to the *Indian Agriculturist*, will be gratefully received. —ED., I. A.

VINE DISEASE.

TO THE EDITOR.

SIR,—I beg to enclose, for publication in your valuable journal, if you see fit, some correspondence between myself and Mr. Minniken, Assistant Superintendent of Hill States, Kanawar, on the subject of the vine disease of that tract.

W. COLDSTREAM.

Deputy Commr. and Supdt., Hill States.

Simla, December 31, 1882.

FROM W. COLDSTREAM, Esq., Deputy Commissioner, Simla, to G. MINNIKEN, Esq., Assistant Superintendent, Hill States, Buzahar Division, Kanawar,—No. 600, dated Simla, the 31st July 1882.

SIR,—I request you will be so good as to ascertain whether the vine disease, which has so seriously of recent years affected the grape crops of Kanawar, is due to the ravages of the phylloxera, or to

some other cause; also what remedies have been tried for the disease, if any, and with what effect.

In order to assist your enquiries, I enclose a wine circular of Messrs. Coyle & Co. of Dublin, which contains an interesting article on the phylloxera, with illustrations.

Copy of letter from G. G. MINNIKEN, Esq., Deputy Conservator of Forests, Punjab, to W. COLDSTREAM, Esq., Deputy Commissioner, Simla,—No. 756, dated Buzahar, the 5th September 1882.

SIR,—In reply to your letter No. 600, dated 31st July 1882, I have much pleasure in sending you a few notes on the vine and its disease in Kanawar.

2. On enquiry I learn that the disease first made its appearance in 1850. At that time every village to the east of Wangtee, as far as Spoo, had its vineyards; they were from one to three acres in extent, situated on terraces immediately above the river, and close under the cliffs which form the walls of the Sutlej gien. The soil in such places is loose and fairly rich, being composed chiefly of the detritus brought down by streams which water them, and of the adjacent gneiss cliffs. In these localities thirteen varieties of grapes flourished, and bore abundant crops of good quality, which were for the most part taken to Hindoostan and China, and exchanged for other produce.

3. The people, on seeing that the disease was spreading, seem to have lost heart, and many have converted their vineyards into grain lands, but no remedy has been tried. The disease has not abated from the first, and the thirteen varieties, which are named, are as follows:—

(1) Mogun, (2) Ohodakhung, (3) Leagoon, (4) Chiligoon, (5) Balba, (6) Ruglasoped, (7) Poregula, (8) Sopdolakhung, (9) Rispruse, (10) Rungaprey, (11) Uratkung, (12) Poedakhung, and (13) Kurmalay Sated; only two varieties, Ruglasoped and Rungaprey, have partially withstood the disease; these however are becoming more and more affected, and their total failure is a question of time, unless a remedy is discovered and applied. In many abandoned or neglected vineyards the vine may be still seen twining among the debris of the wooden frames on which they were formerly supported or climbing up trees. This tenacity of life induces me to think that the disease is not due to the *Phylloxera vastatrix*, and I see from the book you sent me that plants attacked by the phylloxera die out in four years; nor, on an examination of the roots, stem, and leaf, have I found any traces such as are described as belonging to this insect. The fruit appears only to suffer. As soon as the process of ripening sets in, some insect, unknown to me, must puncture the grape and deposit eggs, which become grubs, and cause the grape to split. On looking at the split fruit, I saw many of these, which are not readily seen with the naked eye; they are about a tenth of an inch long, white transparent colour, with a gray spot on top and back of head, and finer than a silk thread. These may be well known; but in the absence of any information about them, I have an idea they may have originated in the rotten wood of the frames. However, they begin to destroy the grape in August, and I shall carefully watch for them next year, and hope to be able to give you further information on the subject. I have now in my garden at Kilba, a vine brought from the Agri-Horticultural Garden, Lahore, which bears a large fine-flavoured red grape, which fruited for the first time this year, and was not attacked. I have heard that a very hardy species which is free from the ravages of the *Phylloxera vastatrix* has been introduced into France with success, and I should like very much to get a few cuttings or plants for trial here.

The Indian Agriculturist.

CALCUTTA, FEBRUARY 1, 1883.

NOTES ON THE CAWNPORE FARM EXPERIMENT.

(10,895 lb OF SALTPETRE CONTAIN 4,978 lb OF POTASH AND 5,716 lb OF NITRIC ACID.)

THE Cawnpore soil is stated to contain, down to the depth of nine inches, 5,717 lb of nitric acid per acre, and as this acid is in combination with potash, we obtain 10,895 lb of that nitrate, which, divided by 2, gives 5,447 lb to every three inches of depth over the acre's surface.

It is further stated that this acre to the depth of 9 inches contained 16,335lb of potash, and if from this the quantity in combination with nitric acid be deducted, there remains of potash 11,356lb, which is equal to 3,765lb to 3 inches in depth of the acre's surface. The nitrate of potash, 3,555lb, added to 3,785lb of free potash, gives, 7,350lb of saline matters to the acre, or 14lb (24oz.) to the square yard, 3 inches in depth, or 8oz. (3,500 grains) one inch in depth, and this, divided by 9, gives 389 grains to the square foot, one inch in depth.

Any soil, so highly impregnated with nitre and free potash, is a *nitrous soil*, and quite incapable of producing a wheat or any other grain crop. But we are told that this soil on being manured with saltpetre to the extent of 240lb per acre gave a remarkable grain crop, yielding 15,605lb of wheat to the acre and a second plot 1,245lb to the acre.

If this assertion is to be credited, then the other one, as to the richness of the soil in nitre and potash, must be discredited.

10,995lb of nitre equal 430 maunds, 16 seers, to every 9 inches of soil in depth, and this, at Rs. 2 per maund, gives Rs. 860 as the value of the saltpetre per acre, against Rs. 58-11-6, the value of 1,605lb. (19 maunds 22½ seers) the value of the wheat crop at Rs. 3 per maund.

If the facts are to be believed, the proper crop to have been obtained from this soil was the nitrate of potash.

* It is evident, however, that a mistake has been made somewhere, and it is quite possible that the soil sent for analysis, was artificially* enriched with nitre and wood ashes before transmission to Roorkee. But if this was not done, then the Roorkee chemist has made an erroneous analysis, which, however, seems improbable, as potash and nitre being perfectly soluble in water, one boil would have removed both from the soil, and being held in aqueous solution, evaporation would have given a saline solution, whose crystals would have yielded saltpetre and the residue potash.

100lb of wheat will yield 2lb of ashes, hence 1,605lb will give 32lb. 1 6/10 ounces of ash.

100lb of wheat ash contain of potash and soda 31lb and of phosphoric acid 46lb. Thus the principal mineral matter needed by wheat is phosphoric acid, to 28lb of potash, and 15lb of lime and magnesia.

Does the analysis mention what quantity of phosphoric acid was present in the Cawnpore soil, as on this component would depend its productiveness in grain?

"The craze among European farmers about nitrogenous manures" had reference to Chilian saltpetre or nitrate of soda. This nitrate contains of soda 31.3 and nitric acid 54.15, whilst saltpetre or nitrate of potash contains of potash 47.15 and of nitric acid 54.15. Hence it follows that nitric acid has a greater chemical affinity for potash, than for soda, and if potash be present in the soil and farmyard manure (which it is), the soda would give up its nitric acid to the potash, and it is to this combination that the increase of produce was due when soda nitrate was used as a manure. An acre of unmanured and gave 2,004lb of wheat, and an acre manured with 1½ cwt., or 165lb. of nitrate of soda, gave 2,806lb. or an increase of 802lb. (see Johnson's *Catechism of Agricultural Chemistry and Geology*, p. 53.) 1,000 parts of a rich English soil contain only 2 parts of potash and 4½ of phosphoric acid; 1,000 parts of a rich French garden soil contained 4.8 of potash salts, and of phosphate of lime and magnesia 5.60 parts: of soda salts 6.70.

J. P. P.

ALOE CULTIVATION.

NOW that the recent experiments in the culture of the *Agave Americana* made in the Hazareebagh district, have proved satisfactory, it will be a matter of surprise if its cultivation on account of its fibre is not extended in many parts of India, not

* By all accounts, a good deal of friction has existed amongst employers of the Cawnpore firm. Saltpetre is made at Cawnpore, and solution of wood ashes concentrated, and added to nitrous earth enriched with saltpetre, would have produced such a soil, which, after being dried, may have been sent to Roorkee.

J. P. P.

only by Government in some of the vast tracts of waste lands which are at present of no value whatever for other cultivation, but by private individuals who may wish to embark their capital in a new enterprise, and who would, no doubt, be able to obtain grants of land at low rates for this purpose. Not only does the actual manipulation of the fibre seem to be extremely simple as appears from the report of the Superintendent of the Central Jail at Hazareebagh, published in a recent issue of the *Indian Agriculturist*, but the cost of cultivation is a mere trifle when compared with that of hemp, jute, and other fibrous plants, the aloe rejoicing in the poorest soil and thriving where no other vegetation could subsist. The young plants having been set out in rows six feet apart, no further care is necessary, such as weeding, breaking up the soil, &c.; and it would even appear that watering the young plants is superfluous, as the fact of its flourishing in dry and sandy soil and on bare rocks would tend to show that it is capable of subsisting on moisture chiefly absorbed from the air; in fact, it is possible that with great care lavished on its cultivation, manuring, weeding, watering, &c., there would be an increase of sap and pulp, and a consequent loss in quantity and strength of fibre. It has been ascertained that the full-grown leaves of the aloe yield about one pound of clean fibre and half-a-pound of tow for every forty pounds of leaves, and that one acre would yield about 1,613 pounds of clean fibre at a gathering, "which," according to Dr. Roxburgh, "may be reckoned on twice yearly after the plants are of a proper age." The present price of the clean fibre in the European markets, we understand, is about £23 per ton, and there can be no doubt whatever that this price, notwithstanding the competition, well remunerates the cultivator after paying all freight and other expenses. There are now no less than eight aloe-fibre cultivating and extracting companies in Mauritius, who, we believe, are working a new process of extracting the fibre, and whose finances are in a very flourishing condition.

It is much to be regretted that a machine has not yet been invented for the economic and rapid extraction of these fibres, which would combine in one operation all the processes of macerating, scraping, washing, and heckling, as most probably the quality and strength of the fibres would be greatly improved, the primitive process of heating and steeping detracting considerably from its value, while there would at the same time be an important saving in labour. Such a machine, we believe, was recently made by Messrs. Price and Lacey of Bombay, but after making satisfactory experiments with a quantity of the wild plant, *A. Vivipara*, they stopped their works through a scarcity of raw material, having based their calculations on a belief that the supply of the wild plant was practically inexhaustible.

Should, however, the culture of the aloe for its valuable fibre receive the attention it deserves, we have no doubt that its extremely profitable nature will lead to a machine being ultimately brought to the required perfection; and as it would in all likelihood be capable of treating all indigenous fibrous plants, such as the *musa*, *Sansivera sylvatica*, &c., which, like the agave, require maceration and scraping, there is no reason why the industry should not eventually become a large one in India, where fibrous plants of all descriptions abound.

A. A. L.

THE SOUTHERN EURASIAN COLONY.

THE Eurasian land scheme in Mysore is an effort of considerable pretensions. We propose giving a brief outline of the objects and aims of the Eurasian and Anglo-Indian Association in regard to this scheme, which looks very well on paper, although it still remains to be seen how it will work practically.

Within the two and-a-half years of its existence, the Eurasian and Anglo-Indian Association of Southern India claims to have accomplished much. It claims to have, to some extent, extinguished pauperism and false pride, modified the tendency towards reckless borrowing, provided work stimulated education, promoted sobriety and economy; in short, to have improved the condition of the Eurasians of Southern India generally, and it is now about to enter

upon the chief work it has set itself to accomplish—namely, that of settling Eurasians and Anglo-Indians on the land. It will try to lead them to undertake agriculture and industrial pursuits, and to remove for ever the feeling of anxiety as regards their own future and that of their children. The Association recognises that this programme is a bold one, but it thinks it is not visionary; for it says that under its tuition Eurasians and Anglo-Indians will see that they are but a section of the people of India, and that they must live like the people, not by artificial support, such as they have received from a sympathising Government, but by general industry, and in harmony with the circumstances around them. To suit the various tastes or means of the community, a variety of pursuits are mentioned as likely to prove remunerative to an intelligent class of people. Since as is stated by the Association, an extensive grant of fertile land has been secured at a nominal assessment, and as capital is forthcoming, it is thought that almost all the elements of successful colonisation are present.

Some time ago, a memorial was forwarded to the Maharaja of Mysore by the Association, asking, on behalf of the community of mixed European and Indian descent, for a grant of land to enable it to carry out its schemes, which were briefly as follows:—To induce and help the community to till the soil, to acquire a knowledge of various trades, to promote education, to foster intellectual ability, and to further honest and healthy ambition,—in fact, to raise the status of the people, both materially and intellectually, impressing upon their minds the dignity of labour. To promote these objects, it was proposed to form small agricultural settlements, and small plantations for the cultivation of coffee, cinchona, tea, and other products for which the climate and soil of Mysore are favourable. In reply to this memorial, the Maharaja issued an order sanctioning the grant of three different blocks of land, amounting in all to 3,900 acres, bearing an assessment of Rs. 2,764. These blocks were selected by the Secretary of the Association, and they have been reported upon by the Deputy Commissioner, who states that they are unoccupied and available to the Association. The conditions upon which these lands are sanctioned are:—free of assessment for the first two years; a quarter assessment for the third and fourth years; half assessment for the two following years, and from the seventh year the full assessment. The grant will be liable to resumption in the event of the Association failing to carry out the object of the concession, which is to encourage agricultural settlements of Eurasians and Anglo-Indians. A further understanding is, that although some encouragement may be needed at the first start, the project, as a permanent institution, must rest upon strictly commercial principles without any special advantages or favours.

Whatever success may be achieved by the Eurasian and Anglo-Indian Association of Southern India, it must be confessed that the movement now sought to be initiated is—provided it is instituted in good faith, and by men who understand not only the requirements of the Eurasians but also their capabilities—an important one, and fully deserving of support. As to whether the Association has over-estimated its own capability we can offer no opinion as we have no other knowledge of its affairs than that we glean from its recently-published guide. Perhaps the view taken by the Association as to the amount of good about to be accomplished is rather too sanguine; a number of reasons combine to make it so, but that, if the scheme can be worked, even on a less extensive scale than is contemplated by the Association, much good will ensue, no one who has paid attention to the depravity and degradation existing among certain classes of East Indians will doubt. This induces another consideration. We presume that it is just this class that it is intended to benefit, but we would ask—are they, either physically or morally, a class of men who might be expected to succeed in a calling where unremitting labour, hard and often unthankful, is, and will be for some time to come, required before even a bare pittance can be expected? We trust that the Committee have taken those probabilities into consideration, and fully weighed the possibilities of failure as well as those of success.

As regards the work now about to be entered upon, the Association is of opinion that, although the ryot succeeds,

the idea that he is the supreme genius of Indian agriculture is a mistake, for his success is identified with the error of being content with as little as possible. It is believed that the field of agricultural pursuits is still open, and only needs capital, energy, and the introduction of new industries and improved methods to make it give a substantial return. Now, all this is very fine, and the intentions of the Association, as they are put on paper, are doubtless very attractive. But it is not safe to accept, as gospel, everything that is said by the Association in its own behalf. The following passage, for instance, which is published in a Madras paper, and written by a correspondent who has lately visited the Whitefield Colony, is not very flattering evidence of what is really being done. This correspondent says:—
‘Very little is being done out at the colonies, and, though all the land has been allotted, only three individuals have commenced work. There are in all five men settled down on the spot; from what I could ascertain none of these had commenced work, as they had no huts to lay their heads in, and the Association refuses all of them a paltry sum to erect cottages. By the kindness of Mr. Marlam, they had all been allowed to live in the hut he had erected. If the Association does not afford those men the little help necessary to erect huts, what is it going to do with the money obtained from the lottery?’

It may be remembered that our Bangalore correspondent, in a letter published on the 13th December, gave evidence to much the same effect. He said that he had been much amused at some of the “laudatory notices of the doings of the Association in some of the up-country papers—notice which have amused me very much, seeing that they appear to have been based on the Association’s published reports, which, as a matter of course, give an altogether *couleur de rose* account of the work and prospects of the institution. We, who are nearer the scene of operations, see things going all ‘aglee,’ and find much more promised on paper than is actually carried out in practice. “Those who have contributed the Rs. 47,000 and odd, which forms the present capital of the Association, are not at all satisfied with the manner in which the funds are being managed; and few will be surprised to learn in the end that the money has been frittered away on a number of utterly profitless undertakings.”

He furthermore said that the land which had been obtained from the Maharaja of Mysore, for purposes of settlement, was not so fertile, nor likely to be so productive, as the Association would have the public believe. He designated the grant as “not even *kanal* lands, but barren wastes.” This is somewhat at variance with the Association’s published report. Referring to “Glen Gordon,” one of the contemplated settlements, the report says:—“It consists of hill and dale, is well wooded, and has the Pennar running at its base. The land is mostly a rich mould, and portions of it have been under the plough. Iron ore of a very superior quality is found in large quantities, and there are distinct traces of the manufacture of iron here in former days. * * * * The land is well suited for the following pursuits—Pisciculture, Sericulture, Vanilla-planting, Sheep-farming, Stock-raising, Apiculture, Coffee-growing, Grape-Vine-growing, Fuel-planting, Date-palm culture, Orange and Fruit-tree-growing.” The other settlements are alluded to in like terms. Our correspondent says on the other hand:—

In the sketch-map of the colony published in the manual, one sees a diagram representing a number of concentric—and I may say eccentric—circles which purport to bound in sites of cottages for the proposed settlers, and provision is made for the school-house, church, and sundry other structures of the kind, but up to date the only foundation which has been laid is that of a proposed school-house. To people of your side of the Vindhya Mountains, the Eurasian Colony of Southern India is apt to appear an established institution, there being the Association’s sketch-map and letter-press description to give outsiders at a distance a general notion of what the colony is to be like, it being easy to allow one’s imagination to fill in the details; but to us on the spot, there is nothing save so many plots of bare land kept waiting for intending tenants who do not evince the slightest disposition to come forward. Those who have applied for lands complain that they have no shelter to go to if they were prepared to take up their settlements, while there is also the fact that the Lottery Committee’s promises as to the ploughing, sowing, and building of cottages, &c., in the first instance, have not as yet been fulfilled.

We are not in a position to judge as to the probability of the work of the Association proving a success or otherwise, but considering the gigantic promises and prospects held out to intending settlers in the manual above referred to, we think that the Association owes it to itself to answer its critics. In the preface to the manual, the following passage occurs: "Calculated as we are, therefore, to take a leading part in the destinies of this country, the sooner we make a settlement on the land, the better. There is every hope of our succeeding. If we make a beginning, we may depend upon it we have seen the end of our troubles. We may increase and multiply after that, but all the better. Mother Earth will never play us false."

As we write other considerations occur to us, but we have not the space to devote further notice to the scheme at present, although we may perhaps recur to it on some future occasion. We must say, however, that unless the Association which is "calculated to take a leading part in the destinies of this country" can answer the very serious charges brought against it, the whole institution runs a serious danger of collapse.

AGRICULTURE IN BRITISH BURMAH.

HOWEVER much public opinion condemns the local Government of Burmah for replacing British officers in the Commission by Burmese, who are not at present so fitted for the performance of the responsible public duties with which they are entrusted, and to the favour shown to Burmese over other classes in minor police and other Government appointments, there can be no question but that the present Chief Commissioner of the province has his heart in his work, and is doing wonders in stimulating the lethargic Burman, so that he may not be altogether replaced in his own country by more active and energetic races. The new Department of Agriculture under Mr. Smeaton is awakening the people to the advantages to be derived from having a dry-weather crop on their fields, from which Burmans have hitherto been only accustomed to get their annual crop of paddy. The fertility of these paddy-fields has made Burmah the great rice granary of the world; but with a little extra labour, and irrigation, and manure, in some places, the Burmese agriculturists might obtain about double their present income from their lands. The wheat of Burmah is said to yield more flour than Indian wheat, and a bushel of it sells for about two and-a-half times the ordinary price of unhusked rice. Yet wheat for British Burmah is mostly imported from Upper Burmah and India, although large parts of the Prome and Thayetmyo districts are as fit for its cultivation as any part of Upper Burmah. Its cultivation in British Burmah would largely develop the resources of the province, and might be carried on in the dry weather when the paddy-fields are left fallow. Tobacco, again, is grown in 12 out of 17 districts yet little over 13,000 acres is the whole cultivated tobacco area, of which nearly one-fourth is in Thayetmyo alone. In Burmah almost every man, woman, and child smokes, so it is hardly surprising to find that nearly 16 millions of pounds of tobacco have to be imported annually into this British province, where climate and soil seem admirably adapted for tobacco cultivation and manufacture. Mr. Bernard wishes to start a tobacco factory where a Virginian tobacco planter will purchase all leaf brought for sale, just as paddy is bought by the merchants now, for cash on delivery, and where the curing, in which the Burmese are not adepts, would be conducted on proper scientific principles. The establishment of such a factory would, it is thought, induce numbers of the people to engage in tobacco cultivation; waste land would be brought under the plough, a new industry would be started which would not only supply the local demand, but create a new export staple for British Burmah. Sugar-cane thrives luxuriously in all parts of the province, and in some parts the land is not even ploughed before planting. In many cases, no artificial irrigation takes place, and the only manure applied is the ash of the grass and jungle burnt over the land in the month of April just before the rains. Little care is bestowed in weeding, the plants being left pretty much to themselves. In twelve months a crop of cane is produced with a sugar-bearing quality superior to most Indian

cane. The local demand is so high that, although in the past five years there has been a yearly increase of cultivation of from 3 to 22 per cent., over 11,000 tons of sugar have to be imported by sea for the Burman market. The high prices obtained by the people for their rice during the past ten or twelve years have no doubt enabled them to purchase imported tobacco and sugar without difficulty, but now that the rice market has fallen to normal rates, and the Agricultural Department is showing Burmese agriculturists what sources of wealth they are neglecting, it is to be hoped the Burmese people will soon be in a position not only to supply all local demands with sugar and tobacco, but to export their surplus crops to countries not blessed with such favorable soil or climate for the production of these articles. Jute, again, is found growing wild all over the province, yet no attempts made to cultivate it by the people, and although the fibre is said to be soft, glossy, and strong, Burmah imported last year from Calcutta jute bags to the extent of £325,351. Supplies of seed were obtained from Bengal last year, and small areas have been selected for experimental cultivation. Mr. Bernard thinks that the labour necessary for separation of the fibre will be a stumbling block to the Burman cultivator, but he hopes this difficulty will be surmounted; and that looking to the enormously developed rice trade of the province, and the consequent demand for jute gunny bags in Burmah where both soil and climate are suitable for the successful growth of the raw material, it is of the highest importance to give the people every inducement to grow the plant as a field crop, as in Bengal, in addition to their paddy.

Although the recent alarming increase in dacoity and violent crime in Rangoon and the Hanthawaddy district is not creditable to the administration, and, according to local opinion, may be directly traced to the reduction in the European staff and the promotion of Burmans not properly qualified in their places, the exertions made to point out to improvident agriculturists the opportunities they are neglecting, and the sources of wealth and independence which are lying open to them, if they will only exert themselves and utilize this magnificent soil and climate all the year round, is worthy of all praise. We trust, before another couple of years are over, to find that the exertions of the Chief Commissioner and his Secretary in the Agricultural Department are crowned with success. When education, wealth, and their attendant, civilisation, have increased to the extent they are likely to do in another decade, the Burmese race will be more fit for the appointments and promotions recently made than they seem to be at present, and no Englishman who knows anything of the province would wish that they should be denied their share of the official "loaves and fishes," when they have proved their capabilities for the higher grades of the public service.

AGRICULTURAL BANKS.

IN the *N. W. P. Gazette* of the 2nd December 1882 appears an Official Paper on the "Agricultural Loans Bill" of 11th November preceding. This paper contains the Council speeches of the Hon'ble Major Baring and Sir Stewart Bayley on the subject. The Agricultural Loans Bill is meant to supersede the Land Improvement Acts of the past, by promoting the establishment of private Agricultural Banks. These Banks are to advance loans to the agriculturist at rates to be officially fixed (according to local conditions and individual cases apparently) and not to exceed 12 per cent. per annum. The Banks are to keep their accounts in a form officially prescribed, and subject to official audit. Loans are to be granted under official sanction for—

- (1) the construction, maintenance, and repair of wells, tanks, and other irrigation works.
- (2) the drainage, and reclamation of land from rivers, swamps, &c.
- (3) the conversion of waste into culturable land.

The Government undertake to recover for the Banks from the principal and sureties all such loans as if they were "arrears of land revenue," and where collateral security exists in the shape of immovable property, by the sale of the latter also, as when "arrears of revenue" are realised; prior rights and interests in the land mortgaged not being prejudicially affected.

Sir S. Bayley shews that the agriculturist borrows from the village usurer for other purposes than "agricultural improvements,"

to which the loans of the proposed Banks are to be restricted. Notably for marriages. But details of his miscellaneous (and to him by far the more urgent and constant, if not the more important) requirements, are necessary here, namely, advances for—

- (1) the Government half-yearly demand; land or water, or both;
- (2) purchase of cattle, milch and draught;
- (3) agricultural implements;
- (4) gold or silver ornaments for the family;
- (5) marriage, birth, and mortuary expenses in variety;
- (6) pilgrimages, bathings, brahmin feasts, and propitiatory and sin-offerings to local deities;
- (7) miscellaneous expenses, down to the *newta* or reciprocal marriage contribution.

The proposed Agricultural Bill ignores all these, and provides strictly for "land improvement" only. Sir S. Bayley correctly holds that the agriculturist who mortgages his property to an Agricultural Bank for this solitary purpose, will certainly be repelled by the village usurer when subsequently applying to him (as he must) for his other requirements, because he will have no security to offer. The agriculturist must, therefore, discard the Bank with all its temptations of low rates of interest and strict honesty in accounts. He will find further, in the non-rigorous demand of the village usurer, an additional reason for preferentially dealing with him. Still more (and this is overlooked by the able Member) the agriculturist need not mortgage *anything* to the village usurer. Acute indebtedness is not chronic everywhere, although through the adverse circumstances of Indian agriculture (which is not farming, but tilling the soil) the agriculturist must frequently and often continuously borrow for his professional and private needs. Thousands of loans are granted without mortgage of immoveable property. Thousands and thousands of transactions occur annually in the N.-W. P. (and elsewhere, too, I should presume), in which loans are advanced to the village *proprietary* of all grades, and to the equally numerous *tenantry* too, *without any security whatever*. It is when debts, too often expanded by falsification of accounts, are not paid, or not attempted to be paid, that the village usurer closes his money-bags, and refuses to grant any further loans unless land or house, ornaments or cattle, are mortgaged. The impunity for fraud which the illiteracy of the agriculturist affords makes the latter, however, a helpless victim more or less *always*. In time, of course, in the case of the thoughtless, imprudent, unwary or unfortunate, decrees with their lamentable consequences follow. Is it likely, however, even in view of all this, that, when an agriculturist, solvent or insolvent, can borrow on a running account, squared or consolidated half-yearly or yearly, without deed or mortgage or lien or pledge, and satisfy all his requirements locally and speedily, that he will trouble himself with deeds, &c., and with delay and harassment under journeyings to and fro to a distance, his trouble all likely wasted and his position rendered the worse, through the discovery and consequent widespread publicity of possible insolvency, in order to get a loan from an Agricultural Bank, simply for *land improvement*? It cannot fail to precipitate the usurer's action against him, and probably against all others suspected of similar effort. It is true that Major Baring proposes, inferentially, to meet the contingency by putting the Agricultural Bank in the position of *first mortgagee*. But this would not meet the derangement of the inter-relationships between agriculturist and village usurer whether mortgagee or not, and it is not by any means certain that the agriculturist would be a consenting party to the transfer of the position of a *first mortgagee*. Whence, after all, is he to get advances for his multifarious needs? Not from the Bank, clearly. Still less from the local Shylock. The securities are all locked up by the Bank. In fact, the much-abused village usurer, infamous as he frequently is, constitutes a most important and essential factor in the social and political economy of the country.

If it is seriously sought to assist the agriculturist at all, it should be thoroughly and in absolute supersession of the village usurer. That the agriculturist needs State aid, is becoming an uncomfortable political fact. The Government exhibit uneasiness on the subject. That some counterpoise to the exactions of the village usurer should be established, is, in the condition to which matters are everywhere assuredly gravitating, a growing social necessity. The Government appear solicitous to devise some measure to that end. But that Agricultural Banks, with restrictions on their operations in terms of the Bill at present before the Council, will afford any relief to the mass of the ever-increasing village *proprietary* who constitute the backbone of the country, is palpably unlikely. The proprietor of hundreds or thousands of acres will doubtless benefit, but his benefit will rarely be any benefit to the country.

To be a counterpoise to the village usurer, the proposed Banks should keep a running account with the village *proprietary*, just as the village usurer does. It might be objected that the proposal is beyond the scope of official intentions and official possibilities. I am not quite sure of impossibilities. As respects the former, the relief of large land-owners by specific measures like the proposed Agricultural Banks is a mistake, when any Bank anywhere will advance loans on their substantial property. Extravagance and incompetence cannot be permanently relieved by the reduction of interest on loans by 6, 12, or even 24 per cent. But any such reduction to the mass of the village *proprietary* will be appreciable, coupled as it will be with emancipation from the frauds of the village usurer. Against the latter the large landholder is tolerably secure. He has those about him who guard his interests,—at any rate, when they do not combine to plunder him. In such case, however, the proposed relief to him is useless, for the State offers him in the projected Banks protection from the local usurer, not from his advisers and environments.

The following scheme of Agricultural Banks for the mass of the agricultural community, rich and poor, comprising substantially the operations of the village usurer (divested, however, of all his forms of exaction) with the features of the Banks contemplated by Government, will likely possess some points of attraction to official consideration.

Some 12 years ago, as administrator, I had to release an estate from suretyship for a mercantile firm to a bank. I had reason to demand and obtain from the Bank a full statement of the firm's account from date of suretyship. The loan for which the deceased had stood security was, what is termed a "Floating Cash Credit"—by which is meant a running account with a stipulated maximum of indebtedness. Suppose Rs. 10,000 is the credit arranged for. The borrower draws it out at once or what he needs, repaying sums to account at intervals, and drawing out others, the bank not permitting the Rs. 10,000 (including interest) to be ever exceeded. When no payments in reduction of debt for six months, such as would comprise interest due and some of the principal, are made, the Bank addresses the borrower and his sureties. These might be with or without collateral security. Failing to ensure an appropriate instalment, the Bank exercises the right of closing the transaction and recovering the debt by action at law against sureties or principal. This is seldom a necessity. It is neither to the advantage of the Bank, nor to the constituent, to close an account. What is the purpose of banking but to have money out at secure interest? As long then as interest and a fair portion of the principal are restored at due intervals, the see-sawing "give and take" of the "Floating Cash Account" goes on, to the satisfaction, convenience, and profit of all concerned. Interest is calculated nominally at 12 per cent. per annum, but manipulated by mutual (!) consent in a particular way, amounts to something appreciably more. The surety or sureties with or without collateral security are necessarily fixtures, while the account runs on probably for indefinite years. The account is terminable only by the borrower discharging the debt.

I propose to apply this "Floating Credit" system with its indefinite periods and its, to all intents, permanently-fixed sureties to Agricultural Banks, as pre-eminently adapted to the exigencies of the Indian agriculturist—but of course without the form and extent of interest. That should never exceed 9 per cent., because of the ample security furnished. It should be calculated on each fractional sum withdrawn and debited at the end of the half-yearly harvests or *faisls*. These will of course vary with locality. The rate of interest should be graduated to a scale of property. The owner of 100 acres and below should be charged 6 per cent.; 100 to 500 acres, 7 per cent.; 500 to 1,000 acres, 8 per cent.; 1,000 and upwards, 9 per cent. The borrower should mortgage immovable property, stock notes, currency notes, promissory notes, whatever he prefers, or whichever he possesses; or where already mortgaged, the Bank should, if practicable, become a first mortgagee by purchase. The exemptions from mortgage should be the agriculturist's cattle (milch and draught), his implements, household goods, and metal ornaments. The mortgage should entail no charges or costs whatever—as stamps, fees, &c. It should be nominal in form but substantial in effect. It will be sufficient to devise a form of application for a "Floating Cash Credit," to which should be attached (or by endorsement on back by the village *putwari* and 2 *lumberdars* or headmen) a detail of the property owned and offered by the applicant—*income or rental, prior mortgage on any of the effects or not, who the mortgagee, what the amount, &c., &c.* These details are sure to be locally known. A mortgage is not concealable, because registered at the

Tehsil—and the detail of fields and houses is part of the village records, copies of which are annually forwarded to the Sudder Station. With the cash debts of the applicant, the Bank should not trouble itself. These would be difficult to discover and would serve no practical purpose. They should not be held to interfere with the Bank's operations, or affect them in any way.

The application and its annexure being forwarded by the Bank to the Collector of the district, he will transmit the same to the Tehsildar for verification. On return to him, the Collector will sanction the amount of the "Floating Cash Credit" to the extent of verification. He will also fix the interest, and the Bank will advance accordingly. This will complete the transaction. If the applicant can give a surety or two with or without collateral security, it will perhaps be often acceptable—but with his immovable property mortgaged, *there should not be any absolute necessity for rigorous conditions.* When the sureties, however, are as substantial as the property mortgaged, the amount of the credit might be enhanced. The other conditions that will regulate the amount of credit will of course be the marketable value of the property mortgaged; or the actuarial value of its rental, or of the income from it. How much below the valuation should be advanced, must be determined according to the possible depreciation of the property pledged. 15 per cent. will likely be found sufficient or more than sufficient in many cases where house property is concerned. Of course, where the position of *first* mortgagee has to be purchased, such outlay will form part of the advance or "Floating Cash Credit." The borrower will then be free to draw up to the amount of his credit, *for whatever purpose needed by him*, and in whatever sum he decides on. He will be charged interest on each sum from the date of its withdrawal, not on the entire sum placed at his disposal; and he can repay from time to time or half-yearly the sums stipulated on, still withdrawing amounts all over the year as needed by him. *In fact, just as he would with the village usurer*, barring the provident limitation of indebtedness, which is entirely in his own interests.

The transition to the new condition of things will therefore be generally in consonance with the agriculturist's feelings and his habitual mode of doing business—and he would find compensation for restriction in debt, in the lower rate of interest and perfect honesty in accounts. In the event of the credit being exceeded by accruing interest (it should not be allowed to do so by overdraws except at the Bank's own risk) or when stipulated half-yearly amounts are not paid, the Government, if failing by notice of action to the debtor to ensure any reduction of debt to an extent, say one-third below the credit, can proceed to recover from principal and surety as if for "arrears of land revenue"; leaving however the debtor free to meet the said limited demand *plus* costs at any stage of the proceedings against him and keep his account running. Provided that once the debtor paid up in full, the transaction should terminate. A fresh account could however be started in the prescribed form.

It might be urged that the debtor would sell his movable possessions to the village usurer on exhausting his floating cash credit at the Bank. He might do many things. If a man determines to drown he will certainly do so. But that is neither here nor there. The suggestion, however, is legitimate that what he is likely to do in a spell of improvident infatuation, or misfortune with his movable goods, he certainly should not be permitted to do with his immovable property pledged to the Bank. In short, *no one should be allowed to assume the position of second mortgagee by advancing money on such property.* He should have no remedy at law, nor any cash credit, against the property mortgaged. This might be held very exceptional procedure, and we might be treated to lengthy sermons on what Carlyle misnamed "that most dismal science," political economy, but the case too is exceptional; and if the agriculturist is to be saved from ruin at all, legislation must take the course indicated.

And what is there peculiar after all in this? The borrower must be a consenting party to the arrangement before it can be carried out. It is not compulsory on him to borrow at 6 to 8 per cent at the Bank, if he prefers to borrow at 18 to 36 and 72 per cent elsewhere. He is simply told at the outset that he cannot be accommodated up to 8 per cent, unless he agrees to certain conditions strikingly in their incidence to anything of the sort elsewhere, *because thoughtfully and conscientiously framed entirely in his own interests.* He is a free agent. Acceptance by him of the conditions offered cannot be construed helplessness, unless a new and novel signification be given to the term. A few years' apprenticeship to the art and practice of economy will do him appreciable good—and the succeeding generation will presumably compare favourably in thrift with the present.

The objection that the agriculturist would by the "Floating Cash Credit" system remain permanently entangled with the Bank, as many are and he once was with the village usurer, would hold good only if he were improvident or had suffered agricultural and other losses; and if he at the same time wished to be free of the Bank. But a reduction of interest up to 24 per cent and the conviction of honestly kept accounts would make even the *provident* and solvent Agriculturist desire to keep his "Floating Cash Credit" always open, if even at a reduced figure, so that he might satisfy his requirements over the year without trouble.

Honestly-kept accounts should of course distinguish the transactions of an agricultural Bank under private management. But what if the impunity which has created the village usurer should affect the Bank too? Safeguards feasible on paper might prove fanciful. Mere accessibility of books to official examination and audit would yield no protection to the agriculturist. Is efficient official knowledge in respect to the payment of sums, or the sums repaid, possible? Sanction for the withdrawal of every sum would not suit the borrower's convenience. It would involve endless trouble all round. What is the testimony beyond a receipt for the actual amounts paid in by an illiterate man, if the receipt proved doubtful? The transfer of the Bank to a Sudder Station for the purpose of efficient official supervision would, by reason of distance from the outlying sub-districts, make the agriculturist resort to the village usurer as of old. The suggestion is that *Banks should be local to every sub-district, and should be officially initiated and managed*, but not by the agency of the sub-district executive. If a private Bank is held able to do a profitable business, which it would, on the terms officially provided, so an official Bank with a paid agency. The already burthened district executive should be spared banker's work. Can the State afford so much capital? Certainly not, if Banks are to be started at once in every sub-district throughout the country. But a commencement can be made in some Sudder Stations, and in some outlying sub-districts, wherever people of capital and property, *who are also local residents*, can be found to take up official agencies under the qualification of suitable security. As time would be required to extend the Banks over the country, the village usurer would have leisure to re-consider his position, reform his distorted views of honesty, and abate his exactions, if he wished to retain his hold on his constituents. He would certainly so wish; and, so wishing, would act accordingly—probably not to the extent of loose anticipation, but there would be sensible reform to the benefit of the agriculturist. An indirect result of establishing Agricultural Banks, it would be a welcome precursor of the Banks themselves.

To prevent the execution of decrees, let the Government at once step in and buy up decrees by notification, and at a fair valuation. These would furnish in every district the nuclei of the proposed Banks, and would serve pre-eminently as advertisements of the Sirkar's project for benefiting the agriculturist, not to be misunderstood, or distrusted by, or misrepresented to, him. The Government might indeed for a time confine itself to buying up decrees until its object and purposes were placed beyond misunderstanding by the "Floating Cash Credit" it would introduce through them. Banks could then be developed from the basis thus established.

In time the Government would feel its way to the transfer of these Banks in the rotation of initiation, or as circumstances rendered advisable, to private agency, with the necessary safeguards in the agriculturists' interests. Not the least among them would be the *personnel* of the Bank employees. These should be always local residents of property and capital as employed by Government in initiating the Banks. These very employees might take over the Banks, instead of their falling into the hands of mere speculators from a distance little in unison or sympathy, if at all, with the agriculturist. The case is not one of ordinary dealing between capitalist and constituent, but vast and important interests are involved. The agriculturist is the financial backbone and mainstay of the country, and it cannot assuredly ever be the purpose to call in capitalists and speculators from a distance, even if bound down with large penalties for misconduct, to make over to them an El Dorado exploited officially with anxious thought and care. There are no parallel conditions anywhere. India is an agricultural country, and State protection of the interests of the agriculturist is a paramount, and to all likelihood, a permanent necessity.

If an Agricultural Bank when transferred to (local) capitalists may grant ordinary loans bearing interest, *i. e.*, other than "Floating Cash Credits," the Government should in no way be responsible for them. The transaction should not be sanctioned, and the Bank should be warned that any rate of interest beyond that which would be charged in the same case on a "Floating

Cash Credit," will not be recoverable at law. This rule ~~will~~ be part of legislation in the matter. For it is clear that any tendency in an *Agricultural Bank* to gravitate to the position and developing practices of the present village usurer is to be carefully checked. The *Agricultural Bank* is for the purpose of superseding the village usurer, affording the agriculturist a cheap running credit to a certain amount, and emancipating him from the usurer's exactions. This purpose, not that of getting hold of the agriculturist's property, is to be kept in view. A lump sum is soon spent, usually mispent; and the ultimate consequence of following embarrassment, is a decree. Indeed it might prove on consideration an important necessity, that *Banks should not travel out of the functions and scope officially assigned to them—viz., to afford "Floating Cash Credits" to the agriculturist.*

It might be urged that the tenant unfortunately cannot in the above scheme share with the proprietor the advantages and benefits of such credit. He has no immovable property to mortgage except some wretched mud and straw tenements. His crops are hypothecated to the proprietor responsible for the Government demand. It cannot, however, be charged as a demerit to a scheme that endeavours to effect so much, that it is not so searching as to reach the tenant. No measure can be framed such as will supersede the principle of the commercial formula, "No security, no credit." Nevertheless, the field of suggestion is not closed here. It does not follow that security is not valuable unless in the form of mortgage, lien, or person. *The borrower's good faith and industry are abundant security:* are, and have been so held for untold years by the village usurer dealing with *tenantry* throughout the country here. Can it be otherwise elsewhere? If so, how are rents paid to the proprietor? Tenants, as a matter of course, possess no land unless they are inferior proprietors cultivating the land of richer ones. They have only the usual mud tenement, milch and draught cattle, and (the better sort) some metal ornaments. Not always are these pawned or sold. The tenant borrows from the usurer, the latter satisfying himself as to the extent of credit he should give: the standing hypothecated crops, a buffalo or two, and a pair of bullocks are viewed and approved. When the crops are garnered, the usurer comes round and receives the whole or such part as the tenant decides to pay to account. With an abundant harvest and high prices, the usurer is cleared off, or if his claim is not satisfied to a certain extent, a heifer or the old buffalo itself, or the pair of bullocks (to be replaced by stronger and younger ones) are ultimately made over to him, most likely at a reduced valuation. But satisfaction of claim partially or wholly is rarely not followed by the usurer's readiness to lend again. As pithily expressed in Bunnesh phrase—

Jo manga so deea,
Jo deea so leea;

or literally—

Gave what was wanted,
Recovered what was due.

At times the tenant, like the small proprietor, gets very much involved. A series of bad harvests, or low prices, or both, are possible calamities. Illness at critical agricultural periods prevents opportune ploughing, irrigation or sowing, and appreciably affects outturn. In such cases the usurer's claim is postponed. Like the tenant he hopes for a better ensuing harvest. If disappointed, or the tenant proves dishonest (the dishonesty of misery) the usurer proceeds to sit in *dharna* on the tenant. A composition is eventually arrived at, unless the tenant has previously disposed of his assets. A law-suit is objectionable, for its outlay, delay, and uncertainty. The poverty of the tenant, simulated or real, and the facility with which discovered movable effects vanish, furnish little to proceed against. Threats followed by the flourish of stamp paper do not always end in a law-suit. The collective sense of the community, proprietary and all, is against *Shylock*, and witnesses will likely be wanting. The general feeling is that he has been served rightly and does not deserve any more payments. He consoles himself by piling on compound interest, and duns the tenant indefinitely. All considered, he is no loser, but he is happy in the misery of a fancied grievance. He nurses it and hands it down to his children, and they hopelessly dun the cultivator's children. How then does a tenant with lost credit find accommodation? In truth he has no difficulty in replacing his *sañ* or banker. He is always a fat constituent. Loans at 24 per cent and upwards, and a few frauds, leave an ample margin to the usurer for losses, so called.

At first sight no *Agricultural Bank* could compete with the village usurer for the custom of the tenant. The risk appears too great. Nor could the Government recover debts as if they were

"arrears of land revenue." His crops are hypothecated to the landlord, and his movable effects vanish rapidly in prospect of danger. The difficulties appear insurmountable. But with *Agricultural Banks* accomplished facts, a system of small "Floating Cash Credits" on the security of two or more of the proprietary, would be feasible, and prove a boon to a hard-working body mercilessly fleeced by the village usurer. Debts could be officially recovered from the sureties as if "arrears of land revenue."

To conclude, If an experimental *Agricultural Bank* of any sort is a necessity in the Deccan for the hopelessly indebted agriculturist there, even more cogent reasons require the establishment of such banks in localities in which like agricultural paucity has not been reached. It is far better to step in and prevent calamity than to grapple with the impossible as (by all accounts) in the Poorundur talook in the Deccan. Bad for the interests and principles at stake, if the Deccan experiment is a test case for the extension of action elsewhere, for it assuredly means failure. There is a world of potency in initial success, I would therefore strongly recommend the trial of *Agricultural Banks* on the lines laid down in these pages, among the *Jat* agriculturists of the Ganges and the two Jumna canals, and in other provinces under like conditions of success.

A. P. W.

BAROUT, MEERUT DISTRICT; }
30th December, 1882. }

EDITORIAL NOTES.

A RESOLUTION in the last *Gazette of India* deals with the question of issuing duty-free salt for use in the manufacture of soap. There is no difference of opinion as to the desirability of relieving the industry of this burden. The question is how this can be done without danger to the revenue. The various provincial Governments have been consulted on the subject, and they are all more or less favourable to the attempt being made under certain suggested restrictions. As there is some difference of opinion among them as to these restrictions, the Government of India, instead of laying down any general rules, has determined to leave each Local Government to make its own arrangements, subject to the final decision of the Supreme Government, to whom they must be reported. "It must be understood that the manufacturer is to bear any extra cost for preventive establishments, &c., which the grant of the concession may necessitate, and that the privilege is liable to be withdrawn if experience shows that it is being abused, or that the revenue is suffering."

We learn from the report on the cotton production and trade of the North-Western Provinces and Oudh for the year 1881-82 that the season was, on the whole, a very favourable one, and that the outturn was greater than that of the preceding year. The total area under cotton during the year under report was 16,37,364 acres, as against 12,70,121 in 1879-80, and 14,19,042 in 1880-81. Of the total of 16,37,364 acres, 3,88,650 acres was land richly manured, 6,27,667 land ordinarily manured, and 6,21,847 was poor land. The average ruling prices of cotton retained for local consumption was lower than in the preceding year, as will be seen from the following table:—

| PRICES PER MAUND (OF 82½ LBS.) COTTON. | | | |
|--|-----------------|----------------|---------|
| 1881-82. | | | |
| First quality. | Second quality. | Third quality. | |
| R. A. P. | R. A. P. | R. A. P. | |
| For North-Western Provinces districts .. | 15 15 4 | 15 9 0 | 13 11 7 |
| For Oudh districts .. | 16 14 6 | 16 11 9 | 14 13 0 |
| 1880-81. | | | |
| R. A. P. | Rs. A. P. | R. A. P. | |
| For North-Western Provinces districts .. | 17 14 6 | 17 0 10 | 15 8 6 |
| For Oudh districts .. | 18 10 11 | 17 4 7 | 16 8 7 |

The average ruling prices realised for cotton exported were also lower than in the year previous.

The total estimated value of the cotton crop for the North-Western Provinces and Oudh is put down at Rs. 2,19,48,462-3-5, made up as follows:—North-Western Provinces, Rs. 2,15,69,826-14-8; Oudh, Rs. 3,78,635-4-9. The gross exports of 1881-82 were 13,45,249 maunds, valued at Rs. 2,01,02,798, as against 11,97,920 maunds, valued at Rs. 1,82,97,980 in 1880-81. Of the total exports, 9,02,562 maunds were consigned to Calcutta. Of this amount Agra contributed 3,08,967 maunds, and Cawnpore 4,20,783 maunds, the balance being contributed by other districts.

From experiments made at the Cawnpore Experimental Farm in the cultivation of Hingunghat cotton and of the varieties of American cotton known as New Orleans and Upland Georgian, on two classes of soil, light loam and a heavier loam, against two varieties of country cotton, it would appear that for light poor soils the indigenous cotton is by far the most profitable, and that on better class soils and with careful cultivation New Orleans cotton can be grown with success and profit.

THE resolution on the forthcoming International Exhibition to be held in Calcutta has been published. The Lieutenant-Governor of Bengal considers that the project, launched by Mr. Jules Joubert, is likely to have a very important effect in developing and promoting the commercial prosperity of India, and he has therefore accorded his sanction and support to the undertaking. The recent Exhibitions in Australia and other Colonies succeeded in giving commerce an impetus, and a like result is anticipated for Indian trade, when the attention of foreign countries is drawn to the great natural wealth of this country; and as the co-operation of Local Governments and Administrations has been invited by the Government of India, there is every reason to believe that the collection of Indian articles will be as complete as possible. Mr. Jules Joubert is an experienced man in such undertakings, and no doubt exists as to his ability to bring the undertaking in India to a successful issue. The 4th of December next is the date fixed for the opening of the Exhibition, and both a general and an executive committee for Bengal have been nominated.

The exhibits will be divided into ten sections, as follows:—(1) Fine Arts; (2) Education and application of liberal arts; (3) Health; (4) Furniture, and other objects for the use and decoration of dwelling-houses and other buildings; (5) Fabrics, including apparel, toilet requisites, and other objects of personal wear or use; (6) Raw products, and manufactures from products not included in other sections; (7) Machinery and implements; means of transport; appliances and processes used in the common arts and industries, including models and designs; (8) Food products; (9) Agriculture and horticulture; (10) Ethnology, archaeology, and natural history. Every facility will be afforded to exhibitors and their agents, in connection with the transport, display, sale, and care of their exhibits, and the utmost precautions will be taken to preserve exhibits from injury, and to guard the buildings; but no responsibility will be undertaken for damage or loss; and exhibitors must make their own arrangement for effecting assurances. Arrangements, with reference to machinery in motion, will form the subject of special regulation. Concerning the arrangements with regard to space, it is announced that the ordinary charge will be two shillings for each of the first 20 square feet, and one shilling for each additional square foot. Exhibitors desiring a frontage to any main avenue for their cases, can obtain it on payment of an additional five shillings per foot of such frontage, irrespective of depth. The general reception of articles will commence on or before 1st October, and will cease one week before the opening. A special jury is to be appointed for the award of gold, silver, or bronze medals or certificates. The Exhibition will be kept open until about the 1st of March 1884. It will be held, as we announced some time ago, partly in the Indian Museum, of which a portion will be set free for the purpose, and partly in buildings annexed to the Museum. These annexes will be commenced immediately by the Public Works Department.

THE honorary secretary of the Calcutta Tea Syndicate has issued a circular, reminding those members who pro-

pose to send samples of tea to the forthcoming Amsterdam International Exhibition, that the latest date now fixed for the reception of samples of the new season's teas is the 4th of February, after which date none can be received. The Committee are now able to state that Mr. Luther Hart, of the firm of Messrs. Hart and Sibthorp, tea brokers of this city, has been appointed to represent the Syndicate at the Exhibition, and also to travel for the purpose of investigating the Russian, French, and other European markets, with a view to encouraging trade in Indian tea, and obtaining the fullest particulars with regard to these markets for the information of the Syndicate.

Attention is called to the notification made in the memorandum recently issued by the Revenue and Agricultural Department, in conjunction with the Tea Syndicate. It is there stated that samples of new season tea may be despatched by parcel post, addressed to the agent of the Tea Syndicate, Amsterdam Exhibition, by any exhibitor who has sent an original consignment. These teas will be substituted, at the exhibitor's request, for those in the bottles previously despatched, but it must be clearly understood that those who have not originally sent samples through the Tea Syndicate cannot be allowed this concession. Samples of new teas must reach Amsterdam not later than 30th June, and measures will be taken by the Government to postpone, if possible, the adjudication of awards for tea until after that date.

The committee will be very glad if a few half-chests of tea can be presented to the Syndicate for distribution in small packets at the Exhibition, and for consumption in the Syndicate allotment of the Indian Court.

THE annual returns of cotton production and trade in the Central Provinces for the year 1881-82, show that there has been a gradual decrease in cotton cultivation in those provinces during the last three years. The total area under cultivation during the year under report was 666,031 acres, as against 756,136 in 1879-80, and 682,962 in 1880-81. The season was very unfavourable for cotton production. In the Chanda, Saugor, Damoh, Chindwara, and Nimar districts, the crop is reported to have been good and well up to the average; but in the districts of the Nerbudda Valley and in the Nagpore and Chutisinghur plains, it is said to have suffered very great damage from the heavy and continuous rains.

The conclusion which it appears to the local Administration may be derived from the fact of the yearly decrease in cotton cultivation, is that cotton would seem to be giving place to cereals in the agriculture of these provinces. It is said that, with the exception of the Wurdha, Chanda, and Nagpore districts, no other part of these provinces is peculiarly fitted for the production of cotton, and it has been reported from some districts that cotton cultivation is giving place to that of wheat and other food grains, now that cotton can be imported at a lower price than formerly ruled for it.

The total outturn of cleaned cotton during the year under notice was 173,328 cwts., and the average outturn per acre was 51 lbs. These figures are higher than those of 1879-80, when the total outturn was 165,760 cwts., and the average per acre 24 lbs., but much lower than those of the year immediately preceding, when the outturn amounted to 262,480 cwts., with an average of 50 lbs. per acre. The highest outturn obtained was in the Wurdha district, where it amounted to 41,847 cwts., and the Saugor district came next with an outturn of 30,141 cwts. In the Nagpore, Jubbulpore, Chindwara, Nursingpore, and Nimar districts, the outturn aggregated 69,095 cwts. Elsewhere in the provinces the outturn was more or less insignificant.

The average ruling prices of cotton retained for local consumption ranged from Rs. 15 per cwt. in the Saugor district to Rs. 32 per cwt. in the Sumbulpore district, while the average prices realised for cotton exported was from Rs. 15 per cwt. in the Saugor district to Rs. 28 per cwt. in the Sumbulpore and Bilaspore districts.

The total estimated value of the outturn of crop was Rs. 39,84,263 as against Rs. 42,81,710 in 1879-80, and Rs. 63,44,300 in 1880-81. As the season was a very unfavourable one for cultivation, the great decrease in the value of the crop may be easily accounted for. There has also, we observe, been a large decrease in the total quantity of cotton exported from the provinces during the year 1881-82,

when compared with the exports of the two preceding years. During the years 1879-80 and 1880-81, the exports amounted to 104,342 cwts. and 174,639 cwts., respectively, while during the year under report the quantity exported was only 94,151 cwts. Of this, 79,305 cwts. went to Bombay and the Berars; 12,444 cwts. to the North-Western Provinces and Bengal; 1,935 cwts. to Cuttack and the Eastern Coast, and 467 cwts. to the Central India States. The shares per cent in the total exports of the last three years taken by each of these places were as follow:—

| | Share per cent. | | |
|------------------------|-----------------|----------|----------|
| | 1879-80. | 1880-81. | 1881-82. |
| Bombay | 51 | 16 | 84.5 |
| N.-W. P. and Bengal | 46.5 | 35 | 13 |
| Central India | 0.5 | 3 | 0.5 |
| Cuttack and East Coast | 2 | 1 | 2 |

THE *Planters' Gazette* says:—"Amongst the articles of export enumerated in a recent report from Kiung-chow is one under the name of Kéuch'a. This is described as a preparation for adulterating tea. The name Kéuch'a, meaning root-tea, is an abbreviation of Lâ-te-shéng-réu, or *Bryophyllum calicinum*, the Chinese term, which implies that the leaf when it falls develops a root, being intended seemingly as descriptive of the characteristic manner in which this plant can be propagated. It grows abundantly on roadsides and waste places in the neighbourhood of Kiung-chow, and its thick and fleshy leaves are gathered all the year round. These are cut into strips, and the pieces exposed to the sun for several days, when, being still slightly moist, they are rolled up by hand so as to resemble tea, and after being completely dried, are ready for exportation. It is satisfactory to know that the export of this spurious tea, which is said to go mostly to Macao, is but a small one, the total in 1880 having been 180,939 piculs, valued at 1,143 taels.

A TRIAL has, it seems, been made of a new machine, patented by Messrs. Death and Ellwood, for extracting fibres, and we understand that it has proved thoroughly successful. The novel feature in it is that the dirt is washed and winnowed from the fibre as it passes through the machine by a jet of water and a fan, and so, by a single process, the fibre comes out clean and ready for use. It has been tried upon aloë leaves, plaintain stems, and hemp, and has, we are told, succeeded with all, but especially with the two former. We may mention that it is of small compass, and costs less than £40.

FROM statistics which have just been compiled, it appears that the production and export of wheat on a great scale is a comparatively new business in the United States. About forty years ago, a considerable quantity was imported from Europe, and in the five fiscal years ending June 1840, the exports were only 1,842,841 bushels. By 1880, however, the aggregate exports had risen to 153,252,735 bushels; the exports of flour for the five fiscal years ending in 1825 amounted to 4,451,384 barrels, or 99.61 per cent of the total of wheat and flour exported. The percentage of flour steadily decreased from that period till 1880, when it was only 15.2 of the whole. Last year it once more rose. Mr. Edmonds, who compiled these statistics, is of opinion that the proportion of flour exported will steadily increase in the future, owing to the popularity of the American article, and the necessity of finding a foreign market for the growing output of the mills. The history of corn in the United States dates from the year 1611, when 30 acres were planted by the James River settlers. Now the fields amount to 62,000,000 acres, yielding 1,500,000,000 bushels, and upwards annually. The exports of corn, compared with the whole crop, are small, but a great deal goes out in the form of meals. The exports for the seven years, 1876 to 1882 both inclusive, were 524,680,520 bushels of corn, which was 168,000,000 bushels more than the combined exports during the preceding 55 years. The total of the six principal grains raised in 1880 was 2,718,193,501 bushels on 120,928,286 acres. In 1881, though the acreage rose to 123,387,770, the yield was 650,000,000 bushels less.

THE information given as to the sources of gutta-percha, and the importance of protecting and of diffusing plants producing it in appropriate localities, fills a noteworthy part of the report on the progress and condition of the Royal Gardens at Kew. The time cannot be far distant, the report tells us, when the natural sources of gutta-percha will be definitely used up. Unlike caoutchouc, which is derived from milky-juged plants of many natural families, gutta-percha appears to be only yielded by species of *Sapetea*, the principal source in Malaya being the plant now known as *Diospyris gutta*. Much requires to be ascertained with reference to the trees yielding Bornean gutta-percha, and much, in view of the fact that the "running out of existent natural sources of gutta-percha is an event within measurable distance," remains to be done in protecting the forests and in developing the culture of the trees in appropriate localities elsewhere. First of all, however, it is necessary to know for certain what are the trees which yield the precious juice, and to do this suitable specimens in a fit state for botanical analysis and determination should be procured. It is obvious, or ought to be, to practical men intent on developing such sources of industry, that the accurate determination of the plant is the first thing to be done, and nowhere can this be better done (if proper material be forthcoming) than at Kew.

MR. LEWIS P. MUIRHEAD, Kiloreggan, writes as follows on the subject of the origin and practice of Ensalage:—

"Sauerkraut? Sauerkraut! Yes, that's it; what is good for man is surely good for beast. I'll try it anyhow." So thought an old German farmer one wet season upwards of eighty years ago, only in carrying out his idea for cabbage he substituted cut grass, clover, and vetches, omitted the pepper-corns, and used a pit in the ground instead of the family barrel or crock (*irdone hagen*).

"Some years after such words as 'Salsfutter' (sated fodder), 'Sauerkraut' (pickled fodder), and 'Viehsolet' (cattle-salad), might be heard among the farmers of Germany and East Prussia, where the practice first obtained a hold, thereafter being carried by emigrants as far as America, and gradually finding its way among the Dutch and French nearer home.

MR. THOMAS CHRISTY, F.L.S., of Fenchurch-street, London, whose work in connection with new commercial plants is well known, has issued a note regarding the kola-nut tree, in which he says:—"I introduced the kola-nut (*Sterculia acuminata*) into England about eight years since, and it has lately been subjected to European analysis, and the result obtained make it exceedingly likely that a large European demand will soon exist. It has been found to contain the same active principle, *vis.*, caffeine, and more of it than the best coffee, and to contain also the same active principle as cocoa, but less fatty matter. Possessing the same qualities as these favourite beverages, it only needs proper treatment to develop a special flavour, and it would then probably be able to compete successfully with those beverages. The nuts are used to form a refreshing and invigorating drink throughout a large portion of tropical Africa, their use being said to support the strength, allay inordinate appetite, assuage thirst, and promote digestion, and to render those using them capable of prolonged fatigue. The Negroes prefer them to tea or coffee, and when they can obtain kola-nuts will not touch coffee. Dr. Daniell says of them:—"It would be difficult to find any product which constitutes such an important article of commerce in Sudan as the kola-nut." Wherever the Negro has been transplanted to a foreign country he has taken the kola-nut with him.

As a medium of exchange for the products of Central Africa, no article could be more advantageous, and on this account alone the tree will well repay cultivation. Moreover, if once introduced as a beverage in civilized countries, the demand for it would soon become enormous.

I have recently been informed by Mr. Espeut, a well-known sugar-planter of Jamaica, that the Negroes use the kola-nut as a remedy for drunkenness; that swallowing a single nut,

ground up and made into a cream or paste with water or spirits, no sign for intoxication remains half-an-hour afterwards. Confirmatory evidence of this property in the kola-nut is given by a surgeon, Mr. Papatho, who tells me that alcoholic drinks do not produce intoxicating effects when the kola-nut is eaten at the same time. It appears, therefore, that the craving for drink, which is such a strong incentive to drunkenness, may be subdued by the use of this reliable stimulant and tonic, as after abusing kola-nut great disinclination is felt to all forms of alcohol. It has also been found to possess a beneficial action on the liver, its continual use preventing attacks of despondency, to which negroes are peculiarly liable. Dr. Daniell records a case of this kind in which the kola-nut put a stop to an epidemic of suicidal mania, which threatened at one time to depopulate the estate on which it occurred.

It is also used by the natives when in a low state of health, and suffering from the skin cracking and peeling on the hands and feet.

Merchants on the West Coast of Africa always have a stock of these nuts, which can be kept perfectly fresh in moss, and when they have a hard day's work to do, they nibble at a nut during the day; this enables them to go through their work without fatigue, and prevents sleepiness.

I have just received from a native gentleman on the West Coast of Africa a fair quantity of fruit in splendid order, as fresh as if just gathered from the tree.

Planters will be able to send them off for seed at once to their estates.

Some have been sent to the leading medical men in London for further experiment, and I am endeavouring to ascertain the best plan of preserving their medicinal properties.

In the December number of the *Agriculturist* for 1882, we published a letter of a correspondent regarding the crushing of mustard seed and the extracting of the oil. We have made enquiries regarding the presses in use, and Dr. Hugh W. McCann, the officiating Secretary of the Bengal Economic Museum, has been kind enough to favour us with a note, in which he says:—

There is no information to be had in the Museum files. An elaborate description of oil presses, as employed in Europe, will be found in Ure's Dictionary under the article *Oils*, but I fancy none of these European presses have been introduced into India. I may refer you to Powell's Punjab Products I, p. 431, and to Dr. M. C. Cooke's report on the oil, seeds and oils in the India Museum, pages 3 and 4, for remarks on the possibility of introducing the simpler kinds of European oil presses, or some modification of them, into India. I heard on enquiry that Messrs. Khetter Mohun Bysack and Sons, of 3, Prosonno Coomarr Tagore's street, had patented an improvement on the native oil press worked by steam, and I applied to them for particulars. They have sent the reply, of which I enclose a copy. Your correspondent states that the output of oil by a native press is about 3 maunds a day. Messrs. Bysack and Sons state that the ordinary native oil mills crushes mds. 1.5 of oil-seeds in 16 hours, whilst their patent press crushes Bazaar mds. 2.10 in 24 hours, or nearly twice as much. The oil extracted would, of course, be considerably less in weight than the oil-seed pressed: so that the figures supplied by Messrs. Bysack and Sons are very considerably less than those of your correspondent.

The following is Messrs. Khetter Mohun Bysack and Sons' description of their patent oil mill:—

A pair of our oil mills takes up a space of 6' x 10'. The mortar is made of wood, and the frame on which it works is made of cast-iron, having a step and a bevel wheel fitted on to it. On the bevel wheel the wooden mortar is attached, and on the side of the frame there is a block, in which the pinion pulley shaft works, and which works the wooden mortar. There are also attached to the frame two 16 lbs rods which hold the upright wooden square stand of 4' on which the friction roller box with rollers is attached.

The two friction rollers press against the side of the mortar, and on the other side of the square stand of wood is a lever of iron, to which is attached a chain with a cap which holds the head of the pestle and presses the oil from the seeds by means of weights hung at the end of the lever.

The mortar is a block of wood hollowed out in a special form and bound with wrought-iron bands.

The pestle is of hard wood. In this there is a considerable advance on the ordinary primitive native oil mills worked by bullocks, which crush in 16 hours mds. 1.5 oil-seed, and which require three bullocks and a man for the working.

Our patent oil mills are driven by an engine at ten revolutions per minute, and the power required is a quarter horse-power.

The mills can crush mustard, poppy, til, linseed and cocoanut kernel, and will crush in each mill in 24 hours mds. 2.10.

The durability of our mills is three times greater than the primitive native mills. The construction is simple and requires no foundation.

The mortar requires to be renewed in 6 or 8 months according to the quality of the wood: the pestle about every month.

Ordinary and not skilled labour is required, and one man can look after the working of six mills.

THE establishment of an agricultural class in the vernacular, for zemindars' sons at the model farm, Hyderabad, Sind, is, we think, an effort of considerable moment, which is likely, we hope, in the future to make its influence felt on Indian agriculturists. There is no royal road to learning, neither is there a royal road to the improvement of indigenous methods in agriculture. This end may be approached from many sides and worked at in innumerable ways, all tending towards the same result. Of all the means used hitherto in India to make some sensible impression on native agriculturists, the establishment of a class for zemindars, such as the one noticed above, is in our estimation the most promising.

COLONEL SLADEN, the Commissioner of Arrakan, found the pepper vine growing wild in the Sandoway district, and a farm under Government auspices was started at Sandoway last year, to see if it was possible to introduce a new article of export for the Arrakan division. The cuttings of the pepper vine grow readily, but it takes three years for them to bear fruit, when they usually last for seven or eight years. The Sandoway farm consists of 623 acres, and by 1885 it will be possible to judge of the commercial success of the undertaking, which, as but little labour is required after the first year, should suit the Burmese admirably. Probably the pepper vine would thrive equally well in other parts of the province, and it would be easy for an acre or two of cuttings to be planted in places where Government already possess experimental gardens, such as at Magargee on the railway line to Prome, at Pahpoon, where the Deputy Commissioner has already successfully grown sugarcane, coffee, and, we believe, tobacco, and at Tounghoo, where Mr. Petley, a private gentleman, has a plantation of coffee, tea, cinchona and potatoes, situated on the elevation of about 2,500 feet above the sea. It is on such hills—and there are many like them in Burmah—that the Eurasian Association of Madras might profitably assist some of the race to make a new start in life. The climate is good, and for the tropics fairly cool for nine months out of the twelve, while almost every description of crop could be profitably raised, or farm produce which would be easily brought to a good market. Will the project of sending butchers' meat from Mysore to Madras, where it is cheap and abundant, ever succeed? In this province, where good meat, milk, butter, eggs are much more expensive, there are good openings for industrious East Indians in this line.

WE desire to call the attention of our readers to the letter on Divi-Divi which appears in our columns, and to the extract on the same subject which we reproduce under "selections". Notes and letters on the same topic appeared in our columns on the following dates—July 1881, page 191; December 1881, page 349; July 1882, page 242; and March 1882, page 69. Actual experiment seems to have placed beyond dispute the very substantial returns which may be obtained from carefully planted tracts of land sown with Divi-Divi. What, however, seems to be wanting is a variety of experiments under different conditions of soil, general treatment, &c., in order to establish conclusively the best methods to be adopted in perfecting and extending this very promising product.

REPORTING on the trade and commerce of Rio Grande del Norte, &c., Consul Bolsham says that India rubber does not appear to progress as it promised, the ultimate extraction showing that the *mangabura* (*Hancornia speciosa*) has become exhausted, the reason probably being that the land where they grow is very dry, and different from the land in the provinces of Para and Amazon.

AN interesting paper on the food value of cotton-seed was recently read by Professor Gulley before the Society for the Promotion of Agricultural Science at Montreal. Estimating the

cotton seed at 10 cents per bushel, and oat straw and coarse hay at 10 dollars per ton, the average cost of food consumed per head per day of cows experimented upon during the past winter was 7 3-10th cents, cows averaging one and-a-half gallons of milk per day. One steer, fed for beef, weighing 700lb, when shut up gained 200lb live weight, or an average of over 4½lb per day, consuming an average of 14 4-10lb of seed per day, and 11lb of straw and hay. Average cost of food per day not quite ten cents. Other experiments, pursued at the State Agricultural College of Mississippi, showed that boiled cotton-seed, with any kind of straw or hay, would cause cattle to fatten rapidly, no matter how poor in condition. It also makes very rich milk, the oil of the seed seemingly appearing in the milk in the form of cream. The quality of the butter, however, when the cows are fed largely on cotton-seed, is poor.

THE International Agricultural Cattle Show, which will take place in Hamburg in July 1883, promises to be a very extensive one. The board of management, in framing the programme of the exhibition, has taken into consideration the different suggestions which have been supplied from agricultural societies in Germany and other countries, as well as from private breeders, and having in this way given general satisfaction, has received support from all parts of Germany. Some doubts which have been expressed by German half-blood horse-breeders, have been removed through an alteration in the programme. Very favourably has that part of the programme been received by the breeders of horses and cattle, which enables the jury to award prizes, which were originally intended for one kind of cattle, to another of which there may be a greater number. At a meeting of the East Prussian horse-breeders, which took place in Insterburg on the 28th October, it was resolved to send East Prussian horses to the exhibition. The breeders from all parts of Germany, north as well as south, have signified their intention to send their cattle to the exhibition. But not only in Germany, but also in other countries the exhibition is receiving particular attention. Committees have been formed in England, Austria-Hungary, Belgium, Holland and Sweden, &c., to promote the interests of the exhibition. The breeders of Switzerland are going to send their produce collectedly, and the government of the country has expressed its willingness to pay their expenses.

THE Council of the Royal Agricultural Society of England have at their meeting of the 1st November chosen six of their members to represent England at the Hamburg exhibition, and to promote the interests of the English breeders. As regards France, the Ministre d'Agriculture has taken in hand himself to induce the French farmers to take part, and the Consul General in Hamburg, Count de Piun de Saint Didier, takes great interest in the exhibition. Russian farmers have already signified their intention to send horses to the show, and American papers are warmly recommending it to the farmers of that country. From all these considerations, it seems certain that the work which has been taken in hand by a number of citizens of the old Illinois town is likely to be a success. Whether breeders of Indian cattle may be induced to exhibit is a matter for speculation; so far as we are aware, there is not much likelihood unless the Government should take the matter up.

THE *Ceylon Observer* has the following:—"The notice of Father Palla's benevolent attempts to establish the silk industry in Ceylon, led us to peruse with fresh interest some notices of Sericulture in Bengal and Mysore, which we found in the *Indian Agriculturist*. For the greater portion of half-a-century now, we have followed the history of experiments to revive what was once an important industry in India. Failure in every case, or at any rate, the slight improvement which has resulted from large expenditure of time, attention, and money, seems due to one cause—the inability of the Indian peasantry, from want of intelligence, or want of care, or both, to spin the silk into decently even thread. It is clear, therefore, that if Europeans do not take up the enterprise of introducing and keeping up a stock of superior worms, and unless the Indian peasantry can be induced to spin

the cocoons into thread more carefully, the enterprise must come to be an end. It seems to be at present kept alive only by the demand for floss silk. The great question as regards Ceylon is—Are our labouring classes, who are likely to be employed in breeding the worms and spinning the filatures of such a superior stamp, physically and intellectually, to the wretched Bengalees, that real and steady good work can be expected from them? We should like to hear the experience of Father Palla and others in this respect.

THE latest use to which the kola-nut has been applied is the manufacture of kola-nut beer. The maker claims for this beer that whilst it is warranted to be non-intoxicant, it contains far more sustaining and stimulating power than an equal quantity of Bass or Allsopp's brew. It is certainly a very palatable drink, and if the temperance party should take it up, there need be no doubt of its success. *S. acuminata* grows about forty feet high, and bears pale yellow flowers spotted with purple; its leaves are about six or eight inches long and pointed at both ends. Under the name of *kola*, or *kolla*, or goora-nuts, the seeds of this tree are extensively used as a sort of condiment by the natives of Western and Central Tropical Africa, and likewise by the Negroes in the West Indies and Brazil, by whom the tree has been introduced into those countries. In Western Africa the trees grow mostly in the vicinity of the coast, and an extensive trade is carried on in kola-nuts with the natives of the interior; the practice of eating kola extending as far as Fezzan and Tripoli. A small piece of one of these seeds is chewed before each meal as a promoter of digestion; it is also supposed to improve the flavour of anything eaten after it, and even to render half-putrid water drinkable. There are several varieties of kola-nuts; the common kind has an astringent taste. Powdered kola is applied to cuts.

THE *Samarang Vanderland* reports that "the company of Dutch capitalists, who have undertaken to open up for trade and industry the 32 islands in the Malaccas known as the Bakian group, has a promising future before it. This company began operations on the 1st January 1881. Since then, a fishing village there, fixed upon as head-quarters, has been transformed into a town, with hospital, warehouses, &c., and 5,000 piculs of dammar have been collected for export this year to Europe, valued at 150,000 guilders. This gum will for the present be the principal export article therefrom, the quantity available being so great that the company counts upon being able to export from the beginning of this year 2,000 piculs of dammar per month at the price of 30 guilders each, thus representing a value of 720,000 guilders a year. Even at this rate, it is said that years will elapse before the old stock can be cleared away; nature meanwhile accumulating fresh supplies. The second product of importance is sago, which can be had for the mere taking, the trees yielding this article forming extensive forests. Next year the company intend to lay out coffee, cocoa, and clove plantations, with coolies from Java, the islanders, from their fewness and laziness, being unavailable for labour."

SIR J. B. LAWES, Bart., writes as follows on ensilage:—

I have recently received from the United States a pamphlet containing an account of experiments with ensilage, carried out at the Agricultural College at Lansing, Michigan. Although these experiments have been conducted with much care and at considerable expense, it has not been thought necessary either to weigh or analyse the maize as it was placed in the silo. We are, therefore, compelled to draw our conclusions as regards these points from the general analyses of maize in flower, and compare them with the composition of ensilage as given in the pamphlet.

The ensilage used in the feeding experiments, as analysed by Professor Neal, gives the following constituents:—

| | | | | |
|----------------|-----|-----|-----|-------|
| Water | ... | ... | ... | 82.27 |
| Ash | ... | ... | ... | 1.24 |
| Carbo-hydrates | ... | ... | ... | 8.08 |

The analysis of the green maize, as given by Dr. E. Wolff, are as follows :—

| | | |
|----------------|-----|------|
| Water | ... | 82.0 |
| Ash | ... | 1.1 |
| Carbo-hydrates | | 10.9 |

We see, therefore, that while the ash has greatly increased, the carbo-hydrates have very much diminished.

In the *Journal of the Chemical Society* for the present year, there is an article by C. Lechartier on the modification which green fodder undergoes when preserved in pits. The analyses were made upon maize and clover. In the unfermented maize, 100 parts dry contain 25 parts of starch and sugar; after fermentation, 15 parts. In 100 parts of clover before fermentation he found 19 parts of sugar and starch; after fermentation, 7½. Alcohol and carbonic acid are found in considerable amounts in the fermented material; there appears also to be a small increase in the fatty matter of the fermented material, but whether this is a food product is not known.

In the experiments upon the feeding properties of ensilage carried out at the New Jersey experimental station, four cows were selected from a herd for experiment. For a period of twenty-eight days all received exactly the same amounts of food, consisting of clover hay, wheat straw, brewers' grains, cotton seed meal, and turnips. During this time No. 1 gave an average of 23½ lbs. of milk daily; No. 2 gave 25½ lbs.; No. 3, 25.6 lbs.; No. 4, 24.1 lbs.

In a second period of twenty-eight days the cows Nos. 1 and 2 were fed with exactly the same food as before; while Nos. 3 and 4 received the same, with the exception that 100 lbs. of ensilage was substituted for 40 lb. of turnips.

Under the same diet as before, the cows Nos. 1 and 2 increased their daily product of milk 1½ lb. and 1 lb. respectively; but those which received the ensilage showed a trifling decline.

It will be observed that the only change in the diet of the cows Nos. 3 and 4 in the second period, was the substitution of 100 lbs. of ensilage for 40 lbs. of turnips. The description of turnips used is not stated, but the dry matter in the 40 lbs. would not amount to more than from 3 to 5 lbs.; while 100 lbs. of ensilage would contain 18 lbs. of dry matter; and this large increase in food we find was followed by a slight decline in milk, and yet ensilage is said to be above all things suitable to the production of milk.

It is stated further that the total cost of growing an acre of Indian-corn, including cutting it up and putting it into the silo, amounted to 41.81 dols., or about £8 14s.; and that the weight of the product from the silo was 40,000 lbs. Assuming that 100 lbs. of ensilage was equal in its milk-producing power to 40 lbs. of turnips, about 7 tons of turnips would be equivalent to 40,000 lbs. of maize. But surely 7 tons of turnips can be grown for a less cost than £9!

I am quite prepared to believe that ensilage is a success in the United States, but, for some reason, which it is not in my power to explain, the evidence brought forward at present, as derived from experiments, is not so much in its favour as we might expect, and we have certainly no crop in this country which could be compared with Indian corn as adapted for the process.

I submit, therefore, that the evidence at our command at the present time does not hold out much inducement for those engaged in agriculture in this country to enter upon the construction of silos.

From a recent report on the trade of Persia it seems that silk, once the staple produce of the country, is not likely to maintain its position much longer. Owing to the silkworm disease, which destroyed crop after crop the peasantry of Chilan have turned their attention to the cultivation of rice, which, as a crop, seems to suit them better, as it requires less trouble to cultivate, and is, moreover, in itself an article of food upon which they principally subsist; it is also extensively exported to Russia. Another article which has

replaced silk is opium. In Kermanshah until ten years ago the cultivation of opium was very limited, not exceeding 675 lbs. a year, required for local consumption. Last year's crop yielded about 13,500 lbs., and it was expected that this year's would realise double that quantity, but it was affected by cold, and consequently did not realise more than 9,450 lbs. From Ispahan it is reported that this year's crop has been partially injured by cold, but that it is richer in juice than that of the preceding year. No change or improvement, it is stated, has taken place in the preparation of the drug, beyond a large admixture of oil introduced to suit the taste of the Chinese, the proportion being about 6 lbs. or 7 lbs. to each chest of 141 lbs. Very low prices were obtained in foreign markets for Persian opium last year, in consequence of which it is said by some that unless prices rise in China the poppy cultivation will not be further extended. The drug is prepared at Ispahan, Shiraz, and Yeza. After being dried in the sun it is manipulated. That destined for China is mixed with oil; that sent to London is exported in its pure state. Persian opium is reported to have lost in the estimation of the Chinese; from this it may be inferred that adulteration must have considerably increased. In Khorasan the cultivation of the poppy has increased tenfold within the last ten years. It grows everywhere in cold as well as in hot districts; every landed proprietor cultivates it, and it may be said that one-eighth of the entire produce of Khorasan is poppy. In Yeza it seems that this year's crop suffered much from cold, resulting in the produce of about half last year's crop. The oil used for mixing with the drug destined for China is linseed oil.

At the instance of the Government of India, the Superintendents of Government Farms, Sydapett, and of the Central Jail, Coimbatore, were called upon by the local Government to consider and report upon certain papers regarding the cultivation of cotton of the natural khaki colour. Mr. Robertson, the superintendent of the Farms, in replying, has forwarded samples of Nankin cotton in the seed, and the clean lint, and states that the cotton has been grown in this Presidency as a botanical curiosity for upwards of fifty years. It was originally imported from China, where the fabrics made from it are in great demand for their cheapness and durability. At one time large quantities of Nankin cloth were exported from China, but its export has now almost ceased. Mr. Robertson does not think the crop is grown anywhere in this Presidency except on a very small scale, but he is putting an acre of land under the crop, and this should in four or five months give enough seed for 20 or 25 acres of land, which will probably suffice for experimental trials. Mr. Grimes, Superintendent of the Coimbatore Central Jail, reports that from two seeds he was enabled to plant at different times twelve acres of land. It is a hardy description of cotton grows, in any jail, is perennial, and gives more than one picking a year. The plant in the field grows to a height of about eighteen inches, but in favourable localities it grows into a large bush, quite four feet in height. He has submitted for inspection some of the cotton in the pod, some hanks of thread spun by the convicts from it, and samples of cloth made therefrom in the jail. Brigadier-General Clerk was supplied with some of this "Nankin" cloth to try its suitability for the summer clothing of troops. Owing to recent orders of Government putting a stop to miscellaneous manufactures in jails, Mr. Grimes rooted up the last field of this cotton, which was planted in 1879, as he thought there would be no further use in cultivating it. He has, however, means of obtaining seed and can recommence its cultivation if necessary. He believes it is not cultivated by the ryots in the Coimbatore district, but is told that it is so in the Tinnevely district. Its great drawback is its shortness of fibre, and Mr. Grimes is anxious to obtain fresh seed from Chunar or elsewhere to ascertain whether it is superior to what he has grown. It will be thus seen that the cultivation of this cotton has passed beyond the experimental stage in this Presidency, and the Government of India have now an opportunity of pronouncing on the merits of a sample of the cloth made from it at Coimbatore. A supply of Chunar seed is to be procured in order that its identity with this cotton may be established. Meanwhile the local Government, we hear, does not think there is any need for extended cultivation here, but that a supply of seed should be maintained for distribution to cultivators in the event of a demand being eventually established.—*Madras Times*.

ARBORICULTURE.

(Continued from page 18, Vol. VIII.)

SAL WOOD is used for cart wheels, and in most localities, in addition to the wheels and axles, the frame-work of carts and shigrams, and rough work, is made of salwood. Salwood is not quite free from attacks of white-ants, and sal planks, the thickest of its kind, will split under the sun, and if thin, will warp; but it resists decay under water remarkably well, for which quality it is extensively used for bridges made wholly of wood. Salwood is not valuable for furniture, because it is not close grained, is not elastic, has no beauty in it, no laminations, and cannot receive high or any polish at all. It is a strong, durable, and rough wood. A century ago we had extensive forests of mature sal in India, at the foot of the Himalayan mountains, ascending up to 4,000 feet both in the territories of the British Government and those of the Maharaja of Nepal; but they have now been mostly used up, and replaced by saplings of 20 or 25 years old; even these are constantly cut down, where the British Government reserved forests do not exist, to supply the wants in house-building. Twenty-five years ago mature sal logs, 100 feet long with a maximum girth of 15 feet, were very common, lying in heaps on the banks of the Gogra and Raptree, now altogether scarce owing to heavy indents by the railways for their buildings, and sleepers. I do not know what these railways will do when the old timber is worked out; because the forests are exhausted of mature trees and the saplings will take 500 to 1,000 years in coming to maturity. Sal saplings grow fast enough in three years' time under favourable conditions, and in the forest, acquiring a height of 30 to 40 feet, having very thick bark, no heart-wood, but mostly soft sap-wood. In the Coosmi forest in the Goruckpore district, and some of the Oudh forests in the Kheri district, I have found sal growing along-side with *Terminalia tomentosa*, 150 feet in height without a bough up to 140 feet. This tree grows from seed sown in June or July, can bear transplanting, but it grows better if the tap-root be not disturbed or mutilated.

NATURAL ORDER, COMBRILACEAE.

Terminalia tomentosa (Roxb.); *H. Asana*.—A lofty, fast-growing tree, very common in the forests of Oudh and N.-W. Provinces, at the foot of the Himalayan mountains. It generally grows in the same forest with *Shorea robusta*, preferring the same soil, climate, and elevation. The pith of the bark of this tree is beautifully red, containing tannic acid, much used by the *Chamars* residing in or near the forest, in tanning leather. *Asana* timber resembles in colour the *shishum*, is somewhat blackish, but is much lighter and wanting in the streaks found in *shishum*. It is neither strong nor tenacious, but can be worked easily enough: fit for pannels of doors and windows. It cannot bear weight, and therefore is not sought after for beams and rafters. *Asana* logs are pretty long and thick. I have seen trees 100 feet high furnishing good mature logs, mostly heart-wood, 60 feet long with a maximum diameter of 4 feet. The saplings and branches are inferior to *sunkhoo*, weak, and soon destroyed by insects. This tree grows from seed sown in June or July.

NATURAL ORDER, SAPOTACEAE.

Bassia latifolia (Roxb.); *H. mahuwa*.—The mahuwa tree is plentifully found in many parts of India. In former years Oudh was well stocked with this tree. Mahuwa is generally 80 feet high with a girth of 12 feet near the ground. Spirit is manufactured from the fleshy corolla, also forming food for cattle and man; the seed is oleaginous, from which excellent oil can be expressed for the manufacture of soap, and the timber, though not suitable for furniture-making and other nice works, is good for well curbs, door-posts, and pannels for doors; it may also be converted into beams for buildings; no rafters, however, can be made, because mahuwa wood of small girth is very weak and not able to bear much weight. This tree is raised from seed sown in June or July. Goats feed on mahuwa leaves.

NATURAL ORDER, CASAREAE.

Casuarina equisetifolia (Forster).—This tree is a native of India, East Africa, and various other parts of the world.

The height is lofty and the girth pretty thick, but the wood is not valuable for any other than purposes of fuel, affording great heat and little ash, well adapted for glass manufacture. *C. equisetifolia* is content with humid sandy soil, where it will grow fast enough and afford abundant supply of fuel in 12 or 15 years. I have raised this tree from seed sown in July, which have attained lofty heights in 20 years' time. They are growing in poor sandy soil at Lucknow.

NATURAL ORDER, AMENTACEAE.

Alnus glutinosa (Gaertner).—The ordinary alder tree of Europe and parts of Asia. It is 70 feet high, with corresponding thick stem. The wood is strong, durable, and waterproof, excellent for under-ground works. Charcoal obtained from the wood of this tree is considered one of the best for gunpowder. Grown from seed sown in September or October.

Castanea sativa (Miller).—This tree, of prodigious size, is very eligible for introduction into India. It is a native of South Europe and the temperate parts of Asia, and therefore will grow well in the lower Himalayas, and tracts at the foot of these mountains, such as Assam, parts of Bengal Proper, Oudh, and the N.-W. Provinces. Its common English name is "sweet chestnut tree," so named on account of its sweet edible fruit. Baron Müller states that a sweet chestnut tree growing on Mount Etna has acquired the great size of 204 feet in circumference of the lower stem, and in other localities diameter of 10 feet of the stem is very common. The timber of this tree is finely laminated, is elastic, strong and durable, and capable of receiving a high polish; hence desirable for furnitures and other nice works. Forests formed of this tree are capable of affording material help in maintaining live-stock with the edible fruit in years of scarcity. The wood also forms choice fuel where it cannot find any other use. Raised from seed sown in September or October.

NATURAL ORDER, SANTALACEAE.

Santalum album et S. rubrum (Linne); *H. chandan, B. khondon*.—The white and red sandalwood trees, so named from the colour of the wood. Small trees 30 to 40 feet high, very slow in growth, and ornamental in appearance. The white sandalwood tree is more common than the red. I have found small trees of both the species growing in large forests in Oudh and the N.-W. Provinces, 20 feet high, with a girth only 4 feet. Young trees do not yield the highly prized aromatic wood, only mature trees having it. Sandalwood is considered sacred by the Hindoos of India, and much sought for; but the wood is scarce and very costly. Forests of sandal trees might be formed in any part of Oudh, N.-W. Provinces, Punjab, Bengal, and Burma. These trees prefer high ground, having lime in the subsoil. Besides the uses the wood is put to by the natives of India, in making marks on their bodies and foreheads in honour of the gods they worship, and aromatic composition of native smoking tobacco, it can be used for furnitures, choice carved boxes, plates, and many other things, the wood always retaining its aroma. These trees are grown from seed sown in June or July.

NATURAL ORDER, RUBIACEAE.

Cinchona officinalis (Linne).—This medicinal alkaloid-yielding tree is the type of the highly-prized and much appreciated *C. ledgeriana*, native of the mountains of New Granada and Peru found growing at altitudes varying from 6,000 to 10,000 feet. The bark is known by the name of 'crown bark' or 'brown Peru bark.' It is comparatively rich in the alkaloids *cinchonidine* and *quinin*. Much moisture is pernicious to this species, and flourishing to the best advantage at high elevation. *C. officinalis* is more delicate than *C. succirubra*. Propagation from seed, cutting, and grafts. Can also be hybridized.

Cinchona succirubra (Pavon).—This species is extensively grown in the mountains of India. It is a native of Peru and Ecuador mountains, requiring the same elevations as *C. officinalis*; but both of them have been grown successfully at lower elevations in India, Java, and Ceylon. *C. succirubra* being found more hardy and quick-growing, is used as stock for grafting *C. ledgeriana* on. This cinchona is poor in the alkaloids compared with *C. officinalis*.

NATURAL ORDER, LAURÆÆ.

Cinnamomum camphora (Nees).—The well-known camphor tree of China and Japan. Small tree, 40 or more feet high, mentioned here as eligible for select plantation in suitable localities. This tree will succeed best on the mountains of lower elevation of Burmah, Bengal, N.-W. Provinces, and the Punjab, and in select localities in Oudh near the Himalayas, free from hot winds of the plains. The product, camphor, is extracted by boiling chips of wood and purifying the reduced matter. Mature trees furnish the largest quantity and best quality of camphor. The wood is valuable for many uses, emitting the fragrant smell of camphor. It is also free from all attacks of insects.

Cinnamomum cassia (Blume).—This cinnamon tree of South China, like the foregoing, will succeed in the same localities. The bark of the twigs supplies the cinnamon of commerce, which is inferior to *C. ceylanicum*.

Cinnamomum zeylanicum (Breyer).—The true cinnamon tree native of Ceylon, growing up to 8,000 feet above the sea in that island, at which height the bark contains less aroma, at lower elevations the aroma being much stronger. The leaves of this, and those of the foregoing tree, yield aromatic oil, and their roots camphor.

The cinchonas and cinnamomums are very choice and highly prized trees, requiring the utmost care and the best localities as to soil and climate for their propagation, hence requiring the special attention of people engaged in the enterprise of supplying India and other countries with their highly valuable products.

The cinnamomums are raised from seed sown in June or July. Seed might be procured from China, Japan, and Ceylon.

NATURAL ORDER, URTICACEÆ.

Morus rubra (Linne).—North American red mulberry tree, 70 or more feet high. It is mentioned here for the sake of its timber, wonderfully strong, compact, and lasting. Grown from seed or cuttings in February, or June and July.

NATURAL ORDER, MYRTACEÆ.

Eucalyptus amagdalina (Qabillardiere).—A very lofty tree, whose colossal structure rears itself up to 500 feet high, with corresponding thick girth. The timber of this tree is strong, elastic, durable, and can easily be worked into any kind of work. House-building, ship-building, railway sleepers, railings, fences, staves, and many other things too numerous to detail, are and can be made of the timber of this tree. It is an Australian tree, being one of the large number of species of the genus *Eucalyptus*, which for the most part fill the Australian forests, and have been found useful in their timber, gum, and tannic acid contained in bark and leaves. These majestic giants of the forest grow very fast and acquire girth and maturity for thousands of years. Some species of the *Eucalypti* have been tried in many parts of India—in Calcutta, Lucknow, Saharanpore, Lahore, and Southern India; and from all personal observations and published accounts, I find them well suited to India, and doing well. They were originally raised from seed, but cuttings obtained from them have also been found to succeed. In exposed localities in the hot plains of India, *Eucalyptus* trees, grown singly at long intervals, do not fare well owing to its quick growth and weak slender stem, liable to be broken down by storms and hurricanes. A fine *eucalyptus* tree in the Lucknow Agri Horticultural Gardens met this fate. When a regular forest is formed of these noble trees, there is no fear of storms and hurricanes injuring them on account of the support of the neighbouring trees. The *Eucalypti* will grow remarkably well within a belt of 200 miles from the foot of the Himalayas, stretching from the Eastern frontier of Bengal to 1,500 miles westward to the Afghan frontier. These trees will grow on poor sandy soil, as I have found them growing on such a soil at Lucknow. Seeds of the *Eucalypti* can easily be procured from Australia, from Baron Müller.

II. CLASS MONOCOTYLEDONEÆ.

NATURAL ORDER, GRAMINEÆ.

To every one in India the name of bamboo is familiar; but every one knows such bamboos only which are found in places

where he is located. For instance, in Oudh, there is one variety of bamboo called *kat bansi*, on account of the long spines, known to botanists by the name of *Bambusa spinosa* of Roxburgh. This bamboo takes up great deal of space, does not grow straight, but from a certain height obliquely and crookedly, crossing other stems, throwing out dense spiny branches, forming impenetrable and formidable bush, which would retard and repel cannon balls (for which quality it used to be planted outside the *gurus*—forts—to baffle and repel the attacks of enemies), by which extraction of the stems becomes very difficult and expensive, and therefore not profitable. Judging from this bamboo, the people of Oudh would shrug their shoulders on hearing of *bamboo cultivation*, being no doubt ignorant of the large number of species free from thorns, perfectly straight in growth, easy of extraction, strong and durable, and useful in multifarious ways. Bamboo in its humble way is as useful, nay, in some instances more, but far cheaper than timber. In China, Japan, and Burmah, houses are built of bamboos, fancy trays and baskets, richly lacquered work-boat masts, fishing, rods, sticks, *morkas* and couches, sericultural apparatus of all kinds, and many other things are made in these places and in India (where available, but in less ingenious fashion). A chief recommendation for the cultivation of bamboo is, that it grows very fast, coming to maturity in 3 to 5 years. In most parts of India the hungalows are made of sun-dried bricks, whitewashed, door and door-posts and windows made of wood, and the rest having bamboo work. When bamboo is not to be found, saplings of *Shorea robusta*, or that of *Acacia arabica* (if available) are used. The bamboo region stretches from the Lower Himalayas to Lower Bengal, the whole of Burmah (British and native), all Siam, China, and Japan, in the continent of Asia. These places have the best bamboo whether for industrial or for decorating purposes: in addition to these, some genera and species highly valuable are also found in South America, parts of Africa situated near the sea, Ceylon and Java, the Philippine Islands and Madagascar. The bamboo genera are very numerous, and have many species and varieties. I will mention some of them which will grow in the plains of India, where this very useful plant is not to be found, forming artificial bamboo forest.

Bambusa aspera (Poir.).—Native of the Indian Archipelagoes. A lofty bamboo, 120 feet high. The stem is thick and very strong: it is straight in habit of growth, and has no spine. Propagated from off-shoots—or from cuttings.

Bambusa vulgaris (Wendl.).—The common spineless bamboo of Bengal. It grows very fast, acquiring the height of 40 feet in one growing season (rainy weather). The maximum height hitherto, under no care whatever, observed, is 70 feet. The stem of this bamboo is extensively used in Bengal for building purposes and is the one known to the people of Western Bengal, N.-W. Provinces, and Oudh by the name of *Chaboo bans*.

Bambusa balcood (Roxb.).—Another bamboo of Bengal, 70 feet high, spineless, strong, durable, easily split and worked into fine slices for manufacturing baskets, mats, &c.

Bambusa Brandisii (Muuro).—Native of the Tenasserim division in British Burmah. The stem is 120 feet high; two feet in circumference, hollow, but pretty thick in the pith, strong and durable. It is spineless.

Chusquea lorentziana (Grisebach).—Sub-tropic Argentina in South America is the native habitat of this bamboo. It is not lofty, only 30 feet high, but is solid, very strong and durable, and affords much material for manufacture of many bamboo things; is also excellent for buildings.

THE MAIJI EXHIBITION AND HORSE SHOW, 1883.

THE Maiji Exhibition and Horse Show for 1883 will open on Monday, the 5th February, and prizes will be issued about eight or ten days after, the intervening days being occupied by the judges in examining and awarding prizes. The date of distribution of prizes can be ascertained on application to the mamedar. All exhibits should be consigned to the mamedar, and should be accompanied by the certificates required by the terms

and conditions connected with each class. Exhibits will not be received after Monday, the 5th, except in the case of perishable articles, which will be received up to the time of examining the particular class concerned. The total value of the prizes amounts to Rs. 5,895.

A.—HORSES AND MULES—60 PRIZES, AGGREGATING Rs. 2,970.

| COLTS. | | Rs. |
|--|--|-----|
| 1. Yearlings, i.e., up to 2 years, five prizes, Ra. 35, 30, 25, 20, and 15 ... | | 125 |
| 2. Colts 2 to 3 years, five prizes, Ra. 40, 35, 30, 25, and 20 ... | | 150 |
| 3. Ditto 3 to 4 years, five prizes, Ra. 45, 40, 35, 30, and 25 ... | | 175 |
| 4. Ditto 4 to 5 years, five prizes, Ra. 50, 45, 40, 35, and 30 ... | | 200 |
| Total ... | | 650 |

FILLIES.

| | | Rs. |
|--|--|-----|
| 5. Yearlings, i.e., up to 2 years, five prizes, Ra. 35, 30, 25, 20, and 15 ... | | 125 |
| 6. Fillies 2 to 3 years, five prizes, Ra. 40, 35, 30, 25, and 20 ... | | 150 |
| 7. Ditto 3 to 4 years, five prizes, Ra. 45, 40, 35, 30, and 25 ... | | 175 |
| 8. Ditto 4 to 5 years, five prizes, Ra. 50, 45, 40, 35, and 30 ... | | 200 |
| Total ... | | 650 |

MARES.

| | | Rs. |
|--|--|-------|
| 9. Country-bred under 13-2, six prizes, Ra. 80, 70, 60, 50, 40, and 30 ... | | 330 |
| 10. Ditto 13-2 and over, six prizes, Ra. 90, 80, 70, 60, 50, and 40 ... | | 390 |
| 11. Stud-bred, six prizes, Ra. 100, 90, 80, 70, 60, and 50 ... | | 450 |
| Total ... | | 1,170 |
| 12. Miscellaneous class for animals deserving of notice, but which are ineligible for various reasons for competing under other classes, Rs. 250, to be divided in small prizes at discretion ... | | 250 |
| 13. Mules, Rs. 250, to be divided in small rewards at discretion to those that have had their mares covered by the Government donkey stallions, and a double reward if the mares are in foal or have foals at foot ... | | 250 |
| Grand total ... | | 2,970 |

TERMS AND CONDITIONS.

Batta at the rate of 4 annas a day for a mare and 2 annas a day for a grass-eating colt, filly, or mule, will be allowed for unsuccessful animals, from the morning of the day of entry on the exhibition rolls to the evening of the day prizes are awarded, and in the case of animals gelded, to date of discharge by gelder. Where an animal is registered after 12 o'clock in the day, only half that day's batta will be allowed. On the special recommendation of the committee, batta will be given for the journey from and to their home to unsuccessful exhibits. A trained gelder will be provided by Government, and all expenses will be defrayed out of the Exhibition Fund.

No prizes are allowed for country-bred colts or fillies, or for mares covered by country-bred horses (no matter how good), as the object is to encourage breeding from Government stallions only. The usual certificates from officers in charge of stallions will have to be produced to prove the breed of young stock, or the covering of their dams.

Animals lean or out of condition will not be allowed to compete. Mares that have received prizes at previous Government shows are not eligible for prizes again, the object being to encourage new animals. Mares must be either covered, in foal, to, or with foal at foot, by Government stallions, or the owners must have them covered at Maiji; without this, they cannot compete. The order insisting upon gelding as an indispensable qualification for a prize is cancelled this year, but where an entire colt and a gelding are equal in merit, the Committee will give the preference to the latter, and a gelding prize winner will receive in addition a bonus equal to the amount of his prize.

Fillies must be stud-bred or they cannot compete.

A consolation class is opened under No. 12.

The prohibition against prize winners of previous years competing again does not apply to young stock, which can of course compete under different ages yearly.

B.—CATTLE, SHEEP, AND GOATS—(137 PRIZES, AGGREGATING Rs. 1,525).

| | |
|---|-------|
| 1. Bulls, 15 prizes, five of Ra. 5, five of Ra. 10, five of Ra. 15 each, total ... | 150 |
| 2. Cows do. do. ... | 150 |
| 3. Bull calves do. do. ... | 150 |
| 4. Cow calves do. do. ... | 150 |
| 5. Field bullocks in pairs, 15 prizes, Ra. 5 of 10, five of 15, and five of 20 each ... | 225 |
| 6. He-buffaloes, 15 prizes as for bulls ... | 150 |
| 7. She-buffaloes do. do. ... | 150 |
| 8. Buffalo calves (bull) do. ... | 150 |
| 9. Do. (cow) do. ... | 150 |
| 10. Sheep, Ra. 50 to be divided in small prizes at discretion, ranging from Ra. 1 to Ra. 5 each ... | 50 |
| 11. Goats do. do. ... | 50 |
| Total ... | 1,525 |

TERMS AND CONDITIONS.

Batta will be allowed for unsuccessful animals from the morning of the day of entry on the exhibition rolls till the evening of the day prizes are awarded, at the rate of 4 annas a day for each bull, cow, bullock, and buffalo, and half this rate for grass-eating calves. No batta will be allowed for unweaned calves, or for sheep and goats. In the case of animals registered after 12 o'clock in the day, only half that day's batta will be allowed. Animals lean or out of condition are ineligible for competing, also those that have received prizes in previous years i.e., grown up live-stock, the object being to encourage new animals; but where young stock are divided into ages, at the discretion of the judges. A prize winner of a previous year, may compete in a class of a higher age this year.

C.—AGRICULTURAL PRODUCE—(86 PRIZES, AGGREGATING Rs. 950).

| | | Rs. |
|--|--|-----|
| 1. Cotton of any variety (except Waradi or old Khandeshi) cleaned or uncleaned 18 prizes, one of Ra. 50, one of Ra. 30, one of Ra. 20, five of Ra. 5, five of Ra. 10, and five of Ra. 15 each, total ... | | 250 |
| 2. Food-grains, 15 prizes, five of Ra. 5, five of Ra. 10, and five of Ra. 15 ... | | 150 |
| 3. Oil-seeds do. do. ... | | 150 |
| 4. Fibres, 10 prizes, five of Ra. 5, and five of Ra. 10 each ... | | 75 |
| 5. Tobacco do. do. ... | | 75 |
| 6. Dyes do. do. ... | | 75 |
| 7. Sugarcane and jagri do. ... | | 75 |
| 8. Vegetables, fruits, flowers, plants, and medicinal drugs, &c., Rs. 100, to be divided in small prizes at discretion, ranging from Re. 1 to Rs. 5 each ... | | 100 |
| Total ... | | 950 |

TERMS AND CONDITIONS.

The quantities exhibited should not be less than the following in the cases given below:—

| | |
|-------------------------------|---------------|
| Cotton ... | 25 seers. |
| Food-grains and oil-seeds ... | 15 do. |
| Fibres, tobacco, and dyes ... | 10 do. |
| Sugar-canes ... | 50 in number. |
| Jagri ... | 1 bheli, |

and should be certified by the mamledar or mahalkari of the district, to be the produce of fields or gardens belonging to the exhibitor.

D.—MISCELLANEOUS—(PRIZES, VALUE RUPEES 250).

Prize for encouraging indigenous art and manufacture (textile fabrics, carts, brass and iron-work, pottery, leather-work, agricultural implements, &c.). Rs. 250 will be divided in small prizes ranging from Re. 1 to Ra. 10 at discretion, care being taken that the market value of the exhibit is not ordinarily exceeded.

| | |
|------------|-----|
| Rupees ... | 250 |
|------------|-----|

TERMS AND CONDITIONS.

These prizes are intended for *bond fide* manufacturers, who must produce certificates from the mamledars or mahalkaris of their district, that they, or the members of their families, manufactured the articles concerned, and that they are for sale at reasonable prices.

No prizes will be given unless the exhibits show some real improvement on the general make of similar articles usually made and sold in the bazaars, and are deserving of notice, owing to special merit, and are of real utility to the public, the object being to encourage progress, improvement, and economy.

OFFICIAL PAPER.

BEE-KEEPING IN INDIA.

GOVERNMENT OF MADRAS, REVENUE DEPARTMENT.

IN continuation of Board's Proceedings, No. 1632, dated 27th June 1882, and the correspondence relating to the question of bee-keeping and the gathering of wild honey in the Madras Presidency, the Board submit the following summary:—

2. Replies have been received from all Collectors.
3. The Collectors of South Arcot, Chingleput, Coimbatore, Kistna, Madras, and Salem state that they can add nothing to the information already published. In the Anantapore district, in six out of the seven talooks, about 300 maunds of honey are produced, the price varying from an anna to an anna and eight pies per seer of 21 tolas. In Madras honey sells at 4 annas a pound.

4. The following extracts from reports are appended.
5. The Collector of Cuddapah, Mr. L. R. Burrows, writes—
I have received reports from Sidhout, Cuddapah, Proddutur, and Rayachoti tahsildars. From these it is gathered that bee-keeping is not practised in this district. The following particulars are gathered from the several reports above mentioned:—

I. *Sidhout*.—Honey is collected in the hills by people of the Mutarachu caste and the Yanadies. The annual produce of the talook may be about 118 maunds, equivalent to about 1½ tons, worth about Rs. 226. It is used principally for medicinal purposes, and, to some extent, as an article of food. There are said to be four kinds of bees: (1) *peddapera*, (2) *chinanpera*, (3) *tahleri*, (4) *musara*. The first kind alone collect honey in considerable quantity, their combs yielding on the average about 2 seers of honey (1½ lb). These bees store their honey in clefts of inaccessible rocks. The taking of the honey is described as follows:—

"In order to extract honey from *peddapera* bees on rocky slopes, eight or ten men, who know all about them, proceed to the spot and draw honey during the day if there is only one hive there, or at night if there be two or three hives at one place. The mode of extracting is as follows:—A chain of bamboo sticks, strongly tied to one another, is fastened by three or four large ropes to a tree or peg on the summit of the hill, and let down into the cave. A few men at the summit catch hold of a rope tied to the waist of the man drawing honey, and also a leather basket and a stick (to press honey to fall into the bag) by means of two other ropes. The man drawing honey then ties a cloth to his head and body, and gets down the chain of bamboo sticks, in order to press the honey into the basket by means of the stick above referred to, when the men at the top burn a bundle of green leaves, grass, and firewood and sling it down by a rope to drive the bees by the smoke. The man in the cave then drags the honey into the baskets and is pulled out by the men at the top. If there be no trees on the top or a peg cannot be pitched into the ground, no endeavours are made to draw honey."

The season for taking honey is June and July.

II. *Cuddapah*.—The Cuddapah tahsildar reports the annual take in the Lankamalai and Palconda Hills to be about 350 maunds.

The names of the four kinds of bees as given by him are as follow:—

Toont-teni or bees in trees and shrubs; *musara-teni*, bees in hollow trees; *toli-teni*, bees in holes; *peru-teni*, bees in rock caves.

III. *Proddutur*.—This tahsildar says the local supply is only about 15 maunds. The best sort of honey procurable in Proddutur bazaar comes from Bellary, and is worth Rs. 2-8 to Rs. 2-12 per maund. The local honey and that obtained from Kurnool is worth about Rs. 1-4 or Rs. 1-8 per maund. There are only two sorts of bees called *Peddapera* and *Toontu*. The former store honey in rock caves, and the latter in walls, hollow trees, &c. In taking honey the bees are driven out by smoke. The hives of the large sort are taken by moonlight.

IV. *Rayachoti*.—The tahsildar says that the Yanadies are the only caste who take honey. He gives the same classification of bees as that given by the Sidhout tahsildar. The annual take is about 20 maunds for the whole talook. The honey season is July and August, with a subsidiary one in November and December.

Extract of report from the Collector of South Canara, Mr. Sturrock:—

| EXPORT. | | | The marginal figures show the quantity and value of the honey exported from and imported into the several ports of this district during the official year 1881-82. | |

the remark in Board's Proceedings dated 16th February 1882, No. 514, that there are periods when honey is reported to be unwholesome on the Nilgiris, I may mention that two deaths from eating honey have been recently reported from the Coondapure talook. I have called for further particulars.

Extract from report from Mr. C. H. Mounsey, Acting Special Assistant Collector, to the Collector of Ganjam:—

The information I give is almost wholly derived from the report of the Udayagiri sub-magistrate, and from it you will see that very little, if anything, is done in trading in honey.

In the division four sorts of honey are obtained, called respectively *bhago* honey, *sathapur* honey, *binchania* honey, and *nikiti* honey. I have been given the following particulars about them:—

Bhago Honey.—This is made by a large and fierce description of bee (hence the name), whose nests are only found on lofty trees and steep cliffs of rock. The inhabitants of Chinnakimodi dare not try to take this honey. In the Goomaur Malahs it is obtained by tying dried palm leaves to very long bamboos, and in the night applying these leaves lighted to the nest. The bees are thereby driven away, the trees are climbed, the comb transferred to pots and brought down. If the trees are too difficult to climb, the nest is knocked down piece by piece by long bamboos. This is avoided, if possible, as the fall to the earth breaks the cells and the honey gets damaged. The honey is extracted by first cutting the comb to small pieces, and then squeezing the honey out. It is thick and very sweet, and is used for food, but it is no use as a medicine. The comb is very large and very full of honey. This kind and the next sort I shall mention are comparatively rare in these hills.

Sathapur Honey.—Bees make this sort in hollow trees or old white-ant heaps. The bees are a smaller and less fierce kind than those which make the *bhago* honey. To obtain their honey, they are driven off with branches, and if their nest is in a tree, it is cut down; if in an ant-heap, dug out. The honey is extracted as the *bhago* honey is. It is not so thick as that, but very sweet and useful for medicine. The cells also have a large proportion of honey in them, and the combs are large. They are built up in seven layers (but what each layer consist of I cannot find out); hence the name *Sathapur*.

The third and fourth sorts, though not very common, are by no means rare in this division.

Binchania Honey.—The bees that make this generally build their nests where smallish branches intertwine. A very large nest will not be more than a foot or so wide and long, and from such a nest only a quarter seer of honey can be obtained. It is a thin honey, not very sweet, but palatable. Its name is said to be derived from the fancied resemblance to the motion of a fan (*binchania*) in the nest as the branches it is built on sway in the winds. The bees not being fierce, the honey is taken in the daytime by lighting a fire underneath the nest, or beating the bees off with branches.

Nikiti Honey.—The fourth sort is found in cracks in walls and *pials*, between timber, or in holes in the ground. The bees are very small (hence the name I am told) and quiet, so much so that children collect the honey. Very little is obtained from one nest, and the eggs of the bee, they say, being bitter, gives the honey a naturally acid taste. The honey is good for eating.

The honey nowhere appears to be purposely collected for sale or barter; but if the Khonds have a good find, having put aside what they want for their own medicine or domestic consumption (it is largely used to quiet children instead of jaggery), the remainder will be sold or exchanged for salt or other commodities at the markets.

Extract of letter from the Rev. E. Bonaventure, Roman Catholic Priest at Surada, to the Collector of Ganjam:—

From my arrival in India I have applied myself to find out some means for the introduction of domestic bees, considering this to be a great improvement in the general domestic economy of the great Indian family. Unfortunately, the few discoveries I succeeded in arriving at on the subject are more theoretical than practical. I don't know of any native or European having succeeded in introducing domestic bees in this forest region. But with the view to a small profit, the Khonds do not neglect the gathering of wild honey—abundant in their forests—to sell it in the bazaars, where it is consumed by natives, who seem very fond of it.

In this place people distinguish six sorts of wild bees. They are called *Oorink* in (1) *Baghu Mohu Matchi*, (2) *Sattopori Matchi*, (3) *Bitichinna*, (4) *Hatti Kanno*, (5) *Tankna*, (6) *Nikiti*. Here are a few particulars about each one of these six species:—

(1.) *Baghu Mohu Matchi* (metaphorically or onomatopoeically so called, because, say the Indians, it is terrible as a tiger) is about the size of our domestic European bee, a little longer, brown, and builds its combs on boughs of largest trees; is approached at with difficulty, and gives but little hopes of being ever domesticated.

(2.) *Sattopori Mohu Matchi* (because it builds no more and no less than seven combs) makes its home in the earth, in the caves of houses, or in trunks of trees; is of a small size—not the smallest—and of a dark brown colour; it does not seem annoyed at the vicinity of human beings, and could therefore be easily domesticated.

Some native people have made the following experiment, which proved, they say, to be successful:—Having discovered a swarm of "Sattopori" bees, they carefully remove the combs of the young nymphae, place them in an earthen pot, and after a few days, see the new bees working in this house as if it were their birth-place.

(3.) *Bitichinna* (make one rod comb of a semi-circular form like a fan); (4) *Hatti kanno* (because of their one comb having the shape of an elephant's ear); (5) *Tankna* (one small comb having the form of the stone of a mosque)—Are three sorts of small bees of a very wild nature, build their houses on the boughs of trees, fear the vicinity of animated beings, and give but little hope of domestication.

(6.) *Nikiti* (which means a small pair of scales), probably on account of the size of the bee and of the little quantity of honey given, is, in my opinion, the smallest bee observed in the country. It works in the trunks of trees or in the cracks of old walls. I now follow the work of a swarm of these interesting little creatures settled in an old wall near the Mission House in Surada. My intention is to prepare for them small hives and try (by still, I don't know what means) to domesticate them. If success answers my

attempt, it will be with the greatest pleasure that I shall report to you its results.

Extract of report from the Assistant Collector, Mr. A. E. C. Stuart, to the Collector of Ganjam :—

The low-country Khonds and Oorlahs that inhabit the wooded mounds of Panchagadotolo, Birkot, Durgaprasad, Darpangla, Gidipaballi, and Sarabadi, at the foot of the ghats, as well as the more remote parts of Jagannadhaprasad and Kurcholy, recognize six kinds of bees, which are locally distinguished as follows :—

(1.) *Bodabagho Mohu Matchi*, (2.) *Sannobagh Mohu Matchi*, (3.) *Satopuri Mohu matchi*, (4.) *Birvidona Mohu matchi*, (5.) *Tenko Mohu Matchi*, (6.) *Nikiti Mohu Matchi*.

This classification is evidently based on the respective dimensions and peculiarities of these winged insects (*matchi*.)

Thus No. 1, being the largest and most formidable, is descriptively called "the big tiger-honey-fly" (*Bodabagho Mohu Matchi*); No. 2, though almost equally dangerous, is somewhat smaller, and is therefore distinguished as the "little tiger-honey-fly" (*Sannobagho Mohu Matchi*); No. 3, though less offensive, is larger than No. 4, from which it also differs in the fact that whilst its combs (*caco*) are arranged in seven layers (*Sattopuri*) tier upon tier, the honey (*mohu*) of No. 4 is contained in a pendent hive (*mohu cako*) attached to its support in the form of a fan (*binchona*); No. 5 owes its name to its peculiarly long wing coverlets within which, as it were, it has its abode (*truko*); No. 6 is the most inoffensive and diminutive of all (*Nikiti* "the last of a series"). I regret that the want of books of reference of entomology prevents my attempting to identify these bees with well-known species elsewhere. It may be remarked, however, that the Khonds *above ghats* do not appear to discriminate so carefully between these different kinds, as I believe all bees are called by one name in the Hills "*(puki bee onga,*"—i.e., "the honey (*puki*) fly (*beonga*)" and their hives "*pukigara*."

The habits of these six sorts of bees, as far as they have been observed, are thus described :—Nos. 1 and 2 make their combs on the highest branches of the loftiest trees, and are only found in the densest parts of the jungle. They rarely remain in the same locality for more than three months, during which time they produce some ten or twelve (Ganjam) seers of honey.

Nos. 3 and 6 frequent hollow trunks of trees and crevices of rocks and walls, which they inhabit for periods of about two years. A season's outturn of honey averages twelve (Ganjam) seers, and being of superior quality, is highly prized.

Nos. 4 and 5 build on boughs of small trees and bushes, and are frequently found in gingelly crops. They appear to be of the most restless disposition, seldom remaining for more than forty days in one place, and consequently seldom yield more than two (Ganjam) seers of honey.

The quality of the honey of these wild bees is decidedly inferior to that of the domesticated bees of Europe, and at times even poisonous owing to the bees having resorted to noxious flowers.

No systematic method of bee-keeping has ever been attempted by the natives of my division, which, as far as I am aware, does not contain a single domesticated bee. I can see no reason, however, why an experimental bee-farm should prove unsuccessful. Melliferous plants and trees, such as the mahwah (*Bassia latifolia*) and kino (*Putea frondosa*), of whose flowers wild bees appear exceedingly fond, grow abundantly; and that honey and wax would be duly appreciated is beyond question, having regard to the fact that the demand in the market is even now sufficiently strong to induce hill and low-country Khonds to bring, from time to time, to Rusaikulonda, Bellungunda, Bodokodunta, and Surada, their uncertain supply.

The honey thus obtained is, after considerable adulteration, locally consumed, the total value of the sales being estimated at Rs. 2,000 per annum.

Though it is doubtless true, as remarked by the Board, that "much of the fertilisation of flowers that is done in England by bees is in India done by ants," I venture to suggest that it is equally true that much of the cross-fertilisation of plants in India as elsewhere cannot be effected by ants, but only by permanently-winged insects, such as bees.

Sprengel was the first to point out that the true function of honey was to secure cross-fertilisation by the attraction of insects; and Mr. Darwin has proved that to effect this desirable object, it is not only necessary that pollen should be carried from a different flower, but also from a different plant. Such transfers can generally only be made by winged insects as bees, which readily fit from plant to plant, and not by creeping insects, as ants, that of necessity crawl from flower to flower.

Moreover, Sir John Lubbock's investigations have shown that certain flowers, if not cross-fertilised by honey-seeking winged insects, could not be so fertilised at all, inasmuch as they have been specially protected by nature from ants that would merely steal their honey without compensating for the fraud by the involuntary gift of fertility,—a boon that could only be conferred by some such winged insect as the bee.

Thus, the marvellous *chevaux de frise* of apices and downward-tending delicate hairs that such flowers as the *carlina* and *lanium* bear, the glutinous exudations from the *limnea*, and the slippery smoothness of certain pendulous flowers, are all typical examples of nature's protection for the perpetuation of these species.

As representatives of all these and many other similar species exist in India, it is manifest that the part played in their cross-fertilisation by such honey-seeking, permanently-winged insects as bees is far from inconsiderable.

The whole question of bee-keeping in India thus acquires not only commercial, but a scientific interest.

Extract of report from Mr. W. S. Foster, Collector of the Godavery :—

"122. *Miscellaneous Products—Honey and Wax.*—There are five different sorts of honey produced in the jungles of this dis-

trict,—(1) *kurra teneh*, (2) *moonur teneh*, (3) *tonudu teneh*, (4) *pitar teneh*, (5) *kunagole teneh*; (*teneh* in Telugu means honey). Nos. 1 and 5 are the most delicate, the wax of both varieties is also good; the former is found in bushes and small trees, the latter in holes in the trunks of trees. The *kunagole* honey is scarce. The combs of both are removed by the hand; the bees do not sting. No. 2 is found in holes in trees, &c.; the wax is good. No. 3 is found in holes in the ground, white-ant hills, &c.; the wax is good. No. 5.—This is the honey of the large bee; it is found suspended in large combs from lofty trees and rocks; the bee is dangerous if disturbed. Honey is not exported, but the wax is collected by Gottelus and Koyas, and sold or bartered to traders, &c. Turmeric is sometimes used to give a yellow colour to the wax."

Mr. H. A. Sim writes from Kurnool :—

The only variety of bee that is known to exist in this district is the large one that builds its combs in great masses on the faces of cliffs or in crevices among the rocks. The Nallamallis are its chief habitat, and the honey is there gathered by Chentus, and by them sold to the nearest Coratias in exchange for grain or other necessities, at the rate of 6 or 8 pies a bottle. It is eventually retailed in the outlying Cutchah villages at 4 or 5 annas, or in Kurnool itself at about 8 annas a bottle.

It is also found in the Yerramallais; the professional honey-gatherers there being a few men of the Boys and Wadder castes, belonging to Panlem and Tamaraipalli villages.

The honey has a slightly bitter flavour, but is otherwise perfectly clear and good, while the wax is white and firm; the hot-weather is said to be the time for taking it, but I have had no difficulty in getting it in the cold weather as well, and it is probably taken all the year round.

I can give no information as to the quantity produced; it can hardly be very much; but such as it is, it finds a ready sale, and there would probably be a large demand for imported honey if it could be sold at a reasonable price.

The mode of harvesting differs slightly in the two places. The Chentus, who has to deal with the comparatively high precipitous of the Nallamallais, lets himself down from above by means of a single continuous line of bamboos, tied together with strips of fresh Madapa bark, and with a long stick in his hand sweeps the comb off the cliff into a cloth that is hauled up by his comrades above. These men are of course excellent climbers and seem to disregard the bee-stings. The Panlem Boys, on the other hand, has only to work among the low cliffs of the Yerramallais; he, therefore, climbs up from below, and, first taking the precaution to smoke the bees off he slashes the combs right and left with his knife and catches the liquid honey as it falls in the large sack-like leather cap that he wears.

Extract of report from Mr. F. E. Robinson, in charge of the Madura Forests, to the Conservator :—

In this district about 10,000 measures of honey are consumed yearly, of which 3,000 are produced in the district, both from Government and private forests. The remainder is imported from Tinnevely, Coimbatore, Salem, and Bangalore districts. About half the consumption is in the Hindoo temples. The honey is sold in the market between As. 14 and Rs. 14 per measure.

Bees are not domesticated in this division. Wild bees make their combs on rocks, boughs, and sometimes in the caves of houses, and honey is gathered therefrom by wild tribes and by Valayers, &c., by the aid of smoke and ladders made of creepers, &c.

The following kinds of bees are found in this district :—

(1.) *Perunthance* or *Malathance*, a large bee with body of a fulvous hue, segments blackish, and wings dusky; body 1.0 inch long. Makes thick honey, which is dark white streaked with red or black. The comb is two feet by one foot, and is found under cliffs at high altitudes, and yields about two measures of honey. It stings severely.

(2.) *Seruthance* or *Puthi rance* or *Kombuthance*; body 0.7 inch long. Found in holes of trees on plains and low hills. The comb is small, yielding scarcely more than one-sixteenth measure of honey.

(3.) *Ponthuthance* or *Thoduthance*; length 0.6 inch. Found in holes of trees and plains, often in clusters. Yield about half measure of honey and half pollum wax.

(4.) *Kosuvanthance*; body 0.3 inch long, very tiny. Seen near foot of hills, and yield scarcely one-sixteenth measure of honey, but one and a-half pollum of wax.

Mr. V. A. Brodie writes as follows to the Conservator of Forests from Malabar :—

I have the honour to report that the practice of bee-keeping is quite unknown to the natives of Malabar.

The wild bees construct their nests on or in trees or rocks difficult of access in the months of February and March, which is the period when the trees of all descriptions flower in this division, and the Mulcers (hillmen) take the honey in April and May before the rainy season sets in. It is roughly estimated that not less than 200 paras of honey are collected from the Government and private forests situated in my division.

There are two kinds of bees, one large and the other small. The larger kind produces a large quantity of honey, locally called *Peruthane* and also wax. This honey is not considered so good as the honey produced by the smaller sort of bees, which is called *Seruthane*. In quantity the latter is comparatively very small, and is considered to possess medicinal properties.

From some places, such as Alathoor, Vadakancheri, &c., honey and wax are carried by Moplah merchants to Calicut and other places for sale.

In a further letter he writes—

Habits.—I do not know whether they hibernate during the monsoon or not, but will endeavour to find out. It is difficult to get any information respecting their habits (*e.g.*, do the young bees collect at the mouth of the old hive before swarming? In what months do the young bees swarm? &c.) from the Mulcers, as they

apparently pay no attention to such details, and when he finds a nest in the honey season, a Muloor promptly rifles it. I will, however, endeavour to get some information on the subject at the time of the Jummabundy settlement.

As in Malabar, or rather in this division, there is an abundance of flowering trees and shrubs, &c., I should think the introduction of bee-culture would be a success if once effected. The domestication, however, of the indigenous bee is not likely to be effected, even if feasible, save by the employment in the pursuit of some one with practical experience of the habits of bees, &c., in other countries or districts. The climate of this coast is so peculiar that I doubt whether foreign bees could be introduced.

Extract of a letter from Mr. Le. Warner, Acting Collector of Nellore:—

I hear that three varieties of honey-producing bees are known in this district.

Rock-bees. Telugu. These bees are dangerous, and their honey can only be collected with great precautions. They are attacked in the night time by a man who is let down the rocks from above, until he is level with the place where the nest has been marked in the day time. By the light of a torch this man places a bucket at the end of a hole underneath the nest. He then pokes two or three holes in the comb; and the liquid honey comes down into the pot placed below. One pot and sometimes two pots are collected in this way from a good nest, and the honey is sold at four annas a viss to the merchants in the neighbouring villages. There are two seasons for collecting the honey in this way—first in April, when the Beera is flowering. This is the best honey. The second season is in November, when the bees feed on the flower of the Cactus (*Bonia jenunda*, Tamil *Sadarakali*). This honey is very hot. I am told that there absolutely no means exist of domesticating this variety of bee.

Palla Tena.—This bee makes a small comb on trees. It is half the size of the rock-bee and not so dangerous. Its comb is easily robbed by knocking it off the tree, after the bees have first been frightened away by noises made under the tree. It is a better sort of honey than the rock-bee honey, but is not collected in such large quantities.

A bee, the size of a fly, called *Koshooou* in Tamil, Telegu. This bee generally makes its comb in the hollow of trees, and has a very small comb. The honey does not taste nice, but is greatly used for medicine in cough, fever, and such cases.

I have obtained most of this information from the Wood Overseer, who knows more about the subject than any of the persons in the district. He is strongly of opinion that the bee indigenous to the district cannot be domesticated. It also has to be observed that the common people among the Sudras have a superstition that the settlement of bees in their backyards is portentous of some evil happening in the family, and it is possible that, for the same reason, they would not regard bee-keeping in the domesticated state with favour.

The Superintendent of the Government Gardens, Ootacamund, writing to the Collector of the Nilgiris, says:—

A few years ago I managed to keep a swarm of Nilgiri bees in a deal-wood box for about three months by feeding them on sugar and water. But they did not appear to be at home in the box, and apparently consumed the honey as they collected it, as there were only a few empty combs in the box when they left it.

The Collector also forwards a letter from Miss Cockburn, of Keta-giri, Nilgiri Hills, to the Acting Head Assistant Collector, from which the following is extracted:—

There are three kinds of bees on these hills, the largest being about an inch in length, builds in almost inaccessible rocks and forest trees, and makes immense hives of three or four feet in depth. These hives are occasionally taken by the Curumbers and Irilars (the wildest aborigines of these hills), who anoint their bodies with the juice of a leaf which grows wild, and which the bees cannot bear. They then let themselves down from the top of the rock with a rattan rope, and after sweeping the bees away, take the whole hive, as they consider the part containing the young bees a great delicacy. Many years ago a gentleman had a very narrow escape, having been chased by a hive of these large bees while out riding. He dismounted and laid down in a swamp, when the bees left him and attacked his horse, which died from the effects of the stings, two or three days after.

The second species of bee is much smaller, and only hives in holes in rocks and trees. We have had this kind in boxes for many years, and found that they succeed well, especially if the garden is well stocked with flower-plants, when they become attached to the locality, and will never leave it. When a hive of this class of bees has been disturbed, they generally cluster on the branch of a tree near till a new abode is found. In such cases, if a common deal-wood box with a little honey spread on the inside, and a small hole cut out at one side, is turned down on a board and placed near the hive, the bees generally find their way into it, or they may be swept into the box at night, and the box replaced on the board. In about a month or so, there should be several combs of honey. All may be taken except one, which should always be left to induce the bees to remain. In the hot season there should be some protection (a little straw or anything placed over the boxes, to prevent the heat of the sun melting the honey-combs as it has been known to do).

The third species of bee is very small and only hives in bushes, and will not remain in a box.

Once in seven years, when the Ruellia is in blossom all over the hills, the honey is very dark, and not considered quite wholesome.

The price of honey here is 12 annas or 1 rupee a bottle.

From Tanjore the Collector writes:—

Three sorts of bees are reported to be found in this district, called the (1) *Kothundi*, (2) *Kolavi*, (3) *Kosavi*. The first is said to be black in colour and irascible. It makes its combs in rocks and trunks of trees. The second sort is generally inoffensive, though

it is possessed of a sharp sting, and is red in colour. It builds on boughs, in the caves of houses, and in trunks of trees. The third is of a diminutive size, and may probably be domesticated.

As regards their domestication only a single instance has been reported. The zemindar of Singavanam, in Pattuottai talook, on information received in regard to bee-keeping in Colombo and the Mauritius, obtained a queen-bee and tied it to a stick by a thread and placed it in the hollow of a tree, and after two or three months a piece of honey-comb, about the size of an egg, was found to have been made by the bees which had been attracted there. The experiment was then abandoned. There seems to be none in this district who are interested in the matter.

Little is known regarding the habits, &c., of these bees beyond the fact that the honey is gathered two or three days prior to the new or full moon. The largest quantity is obtained in the Kodiakadu jungle, Tiruturai-pundi talook, and is sold at 8 annas per measure. It is chiefly used for medicinal purposes and not as an article of food. Whatever quantity is produced is consumed within the district and none is left for exportation. On the other hand, a certain quantity is imported from Ceylon whenever there is a demand for it.

Mr. W. C. Haynes, Deputy Conservator of Forests, Tinnevely, has been at great pains to obtain information. He writes as follows:—

The quantity of honey collected from the Tinnevely forests per annum has varied from 60 to 800 measures, or 45 to 600 Madras seers. It is sold in retail and wholesale.

The profit realized varies from 4 to 8 annas per measure, or 3 to 6 annas per Madras seer, or 4 annas per quart bottle.

None is exported that I am aware of, but is all consumed in the following ways: eaten largely at marriage festivals, as an offering or for anointing gods in heathen temples, and much employed in mixing with medicines.

It is not known how much honey is of a superior quality, as various combs are mixed together at the time of collection.

There appears to be a fair demand, and some is imported, I learn, from the Madura and Palghat hills.

(To be Continued.)

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The usual Monthly General Meeting was held on Thursday, the 5th January, 1883.

W. H. COGSWELL, Esq., President, in the Chair.

THE PROCEEDINGS of the last (November) Meeting were read and confirmed.

The following gentlemen were elected members:—

Managers of the Sungma Tea Association, Darjeeling; of Woodlands, Cachar; of the Nona Tea Company, Assam; of the Otter Indigo Concern, Tirhoot; and of the Equitable Coal Company, Secotampore; Major R. Bartholomew; Major Duncan G. Fitcher; Sheikh Gholam Moheed-ood-deen; his Highness the Nawab of Jaora, and his Highness the Raja of Nursinghur, Bhopal.

The names of the following gentlemen were submitted as desirous of joining the Society:—

F. D. Bellow, Esq., Senior Master Pilot,—proposed by Mr. R. M. Daly, seconded by Mr. J. E. MacLachlan.
S. R. Elson, Esq., Senior Master Pilot,—proposed by Mr. R. M. Daly, seconded by Mr. R. Blochlynden.
J. Leadbeater, Esq., Rankhet,—proposed by the Raja of Kantil, seconded by the Secretary.
Maharaja of Mohurbhunge,—proposed by the President, seconded by Mr. G. L. Kemp.

CONTRIBUTIONS.

1. Suggestions regarding the demarcation and management of the Forests of Kulu. By Dr. Schlich. From the Government of India.
2. Memoirs of the Geological Survey of India,—*Palaeontologia Indica*, Ser. XII, Vol. IV, Part 1, and Ser. XIII. Records of Ditto, Vol. XV, Part 4. Memoirs of Ditto, Vol. XIX, Part 2. From the Government of India.
3. A Manual of the Land and Revenue Systems and Land Tenures of British India. By Baden Powell. From Government of India.
4. Proceedings of Asiatic Society of Bengal, July and August 1882. From the Society.
5. Proceedings of Agri-Horticultural Society of Madras, November 1882. From the Society.
6. *Tropical Agriculturist* for December 1882. From the Editor.
7. Field and Garden Crops of the N.-W. Provinces and Oudh, Part 1. From Government of the N.-W. Provinces.
8. A collection of Geranium plants. From Mr. W. Gollam.
9. Two fine plants of *Magnolia Grandiflora*. From Mr. C. Nickels.

GARDEN.

A report from the Garden Committee was submitted. The Committee intimate they have arranged for an Iron Plant House, to be commenced at once. They allude to the recent consignment of Roses from Messrs. Paul and Sons of Cheshunt. Those despatched in Warden cases had proved a failure; the larger quantity in closed wooden boxes had succeeded much better.

The usual monthly report from the Superintendent was also submitted, of which the following are extracts :—

"The garden has been further cleared of useless plants, but there is a good deal yet to be done in that way. A new ornamental plant catalogue is being prepared, and will be issued in due course; in the meanwhile members desiring a few, but choice plants in their allowance, may have the same by visiting the garden and making their own selection.

"*Eucalyptus citriodora* has taken very kindly to Bengal, and being sweeter scented than *Aloysia citriodora*, 'sweet scented Verbena,' besides growing to a good size, ought to make it a very popular plant, and one that no house should be without.

"The potatoes kindly supplied the garden by Mr. W. Stalkartt have been planted and look very promising; by next meeting I hope to be able to report fully on them.

"The Iron Plant House, now in course of erection, will be found very useful for members and others selecting plants, as being massed in lots, a glance will show what is available.

"I shall in the course of a few days send up to Secretary's Office *Renna luxurians* and *Bahmia Cotton* seed; a fair supply of the former has been collected, and the latter is being gathered.

"The shade thrown by *Oreodoxa regia* has had a peculiar effect on a bed of Rose plants, all within its range having suffered, and to all appearance died down. On removal of the *Oreodoxa regia* the Rose plants recovered their vitality, and I have every reason to believe will do well; this may be worth enquiry, as *Oreodoxa regia* does not appear to have a baneful effect on other plants."

RESULTS OF EXPERIMENTAL CULTIVATION OF KUMAON POTATOS IN THE DARJEELING DISTRICT.

Read a letter, dated 8th September, from the Secretary, Government of India, Revenue and Agricultural Department, requesting to be furnished with a report on the above potatoes, of which a supply was given in February last.

Read the following letter, dated 2nd December, from Mr. H. J. Leitch (Messrs. Lloyd & Co.) in respect to the above :—

"With reference to your letter of 15th September last, enclosing one from the Department of Agriculture and Commerce, regarding the sample potatoes handed to me for distribution in the Darjeeling district, I have now the honour to forward the reports I have received from the different planters in the Darjeeling district, to whom I entrusted the samples for experiment. I can only express my regret personally that the results have not been more satisfactory."

From Mr. W. Helps, Singbala, 12th November, to Mr. H. J. Leitch.—"Your favour of 7th instant to hand, have written to the following gentlemen for their reports on the potatoes I sent them, and immediately on receipt will forward on to you :—

| | | |
|-------------------|-------------------|---------------|
| Mr. H. R. Irwin | ... Punkabaree | ... 1 bag. |
| " A. E. Allies | ... Ring Tong | ... 2 bags. |
| " A. C. Curtis | ... Ting Ling | ... 2 bags. |
| " C. G. Reid | ... Murmah | ... 3 bags. |
| " J. C. Horn | ... Nahore | ... 2 bags. |
| " S. Smith | ... Teesta Valley | ... 2 bags. |
| " H. W. Craigie | ... Gielle | ... 2 bags. |
| " E. Ephgrave | ... Selimbong | ... 2 bags. |
| " G. F. Flamsteed | ... ——— | ... 20 seers. |
| " F. A. Wearing | ... Ambrotia | ... 20 seers. |

"The remainder was put down by me on land belonging to the new Fallochi Tea Co., Ltd., at an elevation of about 4,000 feet, with exception of about 20 seers, which I planted in my vegetable garden at an elevation of about 3,350 feet.

"Owing to the lateness of the season for planting potatoes in the Terai, and the receipt of your private note without date, the instructions contained in Messrs. Lloyd & Co.'s letter of 9th February last for the distribution could not be carried out, so that, in consultation with the late Mr. Forbes Hall, the within mentioned list was agreed to instead. Several wealthy natives of the district were asked to plant some of the potatoes as well, but I regret to say, not one of them cared to do it, or seemed to take the slightest interest in the matter at all."

Report on Potato seed received from Messrs. Lloyd & Co., Calcutta, as per their letter of 9th February 1882.

"3rd March 1882.—Planted in my vegetable garden at about an elevation of 3,350 feet, ten seers of small tubers in trenches well prepared with ashes, lime, and manure, each trench about 2½ feet apart, and potatoes sown about eight inches apart, the tubers were very small with all eyes but one picked out, nearly every one sent up vines, which grew exceedingly well, and formed good substantial looking plants, necessary earthing up was done, and when the whole of the vines had completely dried, were dug up in the month of July, result being only 20 seers of very poor, indifferent small potatoes; any number of the vine roots being taken up, without the slightest sign of a tuber having been formed. Red ants very destructive.

"Planted in my vegetable garden at the above elevation ten seers of the largest size tubers cut into four and five pieces, put into well-dug-deep trenches, manured last year with cowdung, and in which nothing had been grown since it was manured, soil was beautifully prepared, pulverized, and forked deep to about one and-a-half feet; dug up in July, result about thirty seers, not one of the tubers being equal in size to what were planted, as with the small ones; any number of the vine roots not having the slightest sign of a formation on them whether from having been in a very young state, destroyed by red ants, or not, I am unable to say, but I find them (red ants) very destructive up at this elevation, and do all I can, I cannot rid the place of them, for I have burnt the soil, used ashes and lime to a great extent and still of no very great beneficial avail. March 4th, 5th, 7th, 8th, 9th, and 10th, planted nine maunds one seer at an elevation of about 4,000 feet, putting some down whole, some cut into four and five pieces, and

some treated as the small tubers were planted on the 3rd in my vegetable garden. The land selected had not been cultivated for some six years past, a rich red looking soil, cut the jungle on it first and allowed to dry, then fired it for the ash, deep-hod it once, and then sprinkling well with lime, forked it deep, taking out all roots, stones, &c., and pulverizing the soil as much as possible, planting the potatoes on drills as is the native custom up in the district, earthing up as well and not a weed allowed to grow, for one coolie was kept constantly on the field for this purpose, and also to protect it from being robbed at night, it was strongly fenced round also, to keep animals and cattle out, and I should say the land planted out was from ½ to an acre in extent. On being dug up in September, many tubers were found to be half-rotten, and many more had thrown out new vines four to five inches long; this, I am inclined to think, shows that the elevation there is not suited for potato growing, and seems that it is neither one thing or the other. Root upon root was dug up, without a single formation of a tuber, and any number of others with only one tuber, in which case, it invariably was a fairly large one, with a red skin; some of the white skin roots gave five and six tubers, but only one could be called medium size; result of produce about twenty-seven maunds, or about three maunds for every one maund planted, which is a very poor yield indeed, and plainly convinces me that potatoes will not grow well unless in a soil that retains moisture, and in a medium temperature, and at an elevation of about 5,000 feet or so when planted in February or March, or on the plains in September or October, when there is a very good amount of forcing heat and a good amount of moisture in the soil retained after the closing in of the rainy season to assist the development of the tubers after forming. I have experimented up here now for the last six seasons with potatoes, and signally failed each year. In all other ordinary garden produce I have been most successful, which convinces me that I am not altogether to blame for the failure, but that the elevation and soil is not suited, and would never pay to cultivate the potato, no matter if the very best seed possible could be procured and planted.

In conclusion, I can most conscientiously say that I devoted a great deal of time and attention to the preparing of the land and the planting of these tubers, but regret exceedingly the thing has turned out so miserable a failure.

From Mr. H. M. Leonard, Goomtee Tea Co., Ltd., Kurseong, 14th September 1882.—Yours of the 9th February, anent cultivation of potatoes, to which I replied on the 14th February 1882. I distributed the potato seed amongst some of my people, and also planted a quantity under my own supervision, but found nearly in every case that the seed rotted and in other cases yielded but a poor crop, of small waxy potatoes, the size of bullets. The accompanying figures will show the percentage of some of the seed planted, viz., from 20 seers seed 80 seers potatoes all very small, and from 16 seers seed 40 seers potatoes also small, and fully half were rotten and not fit for use.

From Mr. E. Ephgrave, dated Selimbong Estate, Nagriapora, 14th November 1882.—Your post-card to hand. The two bags of potatoes you sent to me were in very bad condition, many of them rotten, evidently through being confined in the bags too long, consequently only 90lb. were fit to sow, which produced, as near as I am able to ascertain, about 470lb. Soon after they were sown I left for England, and the party I left in charge did not take any account or trouble with them. I have been given to understand they were greatly eaten by insects, but I did not see the potatoes myself.

From Mr. G. F. Flamsteed, dated Nahore, 19th November 1882.—Here is the Rev. Wilson's report on the potato seed I gave him.

The bag of seed was in a very advanced stage for sowing, and yielded 27 seers for sowing only; produce close upon 3½ maunds, not very large or small; quality good; these I have saved for seed, as the first time is no criterion.

From Mr. A. O. Curtis, dated Ting Ling, 18th November 1882.—In reply to yours of the 10th about the potatoes, I am sorry to say they were a failure with me: most of them were destroyed by red-ants before they came to maturity.

From Mr. F. A. Wearing, dated Ambrotia, 15th November 1882.—I duly received your post-card and here is the answer.

I gave some to a sirdar, who planted them at about 4,000 feet elevation at the time you gave them, and they came up fairly well. I really cannot tell you the exact kind of soil, though I suppose it might be called a light clay.

Others I planted down near the Jorah that runs through our garden in first class soil, but it is too wet for them to succeed so low in the rains, and though some came, the majority rotted. I have planted another crop just at the close of the rains, and I think they should do well.

From Mr. S. Smith, dated Teesta Valley Tea Company, Limited, Darjeeling, 21st November 1882.—In reply to yours of the 10th instant, regarding the seed potatoes which I received through you, I beg to state that I planted out some of both kinds on after their arrival (the 23rd February); this seems to have been too late in the season for this place; the weather by the time the potatoes showed above ground, had become pretty hot, causing too rapid growth. The stems produced were enormous in size, and the tubers were both large and abundant, but the rains were on us before they were ripe, so that on digging up a plant, only about one-third of the tubers were fit for use, the larger ones were rotten, and the smaller unripe. I have no doubt had they been planted from six to eight weeks earlier they would have been an enormous crop.

On one plant (the white kind) I counted no fewer than 66 tubers; the average return was about ten times, but had they been ready before the rains set in, it would have been nearer twenty.

The quality of those fit for use was excellent.

Resolved.—That the best thanks of the Society be given to Mr. Leitch for the trouble so kindly given towards this trial.

INTRODUCTION OF CERTAIN FRUIT TREES INTO THE FIJI ISLANDS.

The following interesting letter from John B. Thurston, Esq., Colonial Secretary at Fiji, dated 10th October, was next read:—

"I have to acknowledge with many thanks the receipt of your note dated the 28th June, together with a case of mangoes and lichees per ship *Poonah*.

"Your communication would have received earlier reply but for the unusual pressure of my official business, consequent upon the removal of the seat of Government from the island of Ovalau to that of Viti Leon.

"It is with pleasure that I now am able to inform you as to the results of your kind and very valuable donation.

"The lichees, with two exceptions, were all alive. They have been planted out in appropriate situations, and are in a fair way of establishing themselves.

"A few lichees had been previously introduced by planters returning to the Colony *via* Ceylon, but I am not aware that they were established in any one case. The same may be said of Rambutan, Longan, &c.

"You are probably aware that a congener of the lichee, *viz.*, *Nephelium pumatum*, is indigenous to Fiji. It is a very fine tree, and bears a very agreeable fruit. But you have it, I believe, in many parts of India. [Not in the Society's Garden.]

"Of the mangoes, a fair proportion were alive. Those dead were as noted in the margin. The plants had experienced some very cold weather, and had, I think, suffered a little from the not uncommon mistake of being supplied with too much water. Upon the whole, however, Mr. Cornelius landed his charge in very fair condition, and has well earned my thanks.

"The names in the margin are most likely improperly spelt, there being much difficulty in reading some of the labels, but may serve to indicate the varieties lost.

"In consequence of the early departure of Mr. Cornelius to his post at a somewhat distant part of the colony, I was unable to consult him as to what plants in this colony would be acceptable to your Society.

"But until he has been here some little time, it is not likely that he would have, upon such a point, much advice to offer.

"I shall therefore fill your case for return per 1st January, and ship in May next, exercising my own discretion as to its contents, though in the meantime if you can give me any suggestions yourself, it will give me pleasure to act upon them.

"This colony appears to present conditions of soil and climate favourable to the growth of a number of tropical productions, and with the assistance of the older colonies and dependencies of the Crown might soon possess them.

"Dr. King has very kindly sent me from time to time a number of trees and seeds of economic value, and they are doing very well.

"With the present rapidity of steam communication, I find, however, that the post is a most useful agent, as by the transmission of fresh seeds the probabilities of a useful introduction are increased, and the risks to individual plants avoided.

"If, therefore, it is within the power of your Society to send me seeds of any useful fruit or timber trees, or of any ornamental plants, it will confer a benefit on this young colony.

"I have succeeded in obtaining a grant of land, or rather a reservation, for the purpose of forming nurseries and gardens for the propagation and culture of useful and ornamental plants and trees, the management and control of which I have undertaken myself until such time as the finances of the colony will permit of a professional officer being appointed.

"Sir Joseph Hooker and Mr. T. Dyer have both taken great interest in the task I have set myself, and will learn with pleasure of the valuable and quite unexpected assistance you have been so good as to give me."

Resolved—That the acknowledgments of the Society be tendered to Mr. Thurston for his interesting communication, that a supply of seeds be forwarded to him, and that his offer of reciprocity be thankfully accepted.

JAPAN PEA.

Read a note from the Superintendent of the Botanic Garden, Saharanpore, forwarding a small paper of the Japan pea (*Soja Alepica*), and promising a larger quantity on receipt of a supply shortly expected from Japan.

The Secretary stated that this pea has been brought to the notice of the Society some 38 years ago, as the following extract from its proceedings for August 1844 will show. A correspondent (Captain Biggs,) presenting an assortment of seeds from China, makes the following remarks in regard to one kind, which is doubtless the *Soja Alepica*:—

"Of the esculents the large white pea is deserving of this notoriety, that it forms the staple of the trade of Changhair, or nearly so, to the astonishing amount of 10 millions of dollars, or 2½ millions sterling. This I give on the authority of the Rev. Mr. Medhurst of Changhair, and Mr. Thom, H. M.'s Consul at Ningpo. The peas are ground in a mill and then pressed, in a somewhat complicated, though as usual in China, a most efficient press, by means of wedges driven under the outer part of the frame-work with mallets. No description would suffice without a drawing. The oil is used both for eating and burning, more for the latter purpose, however, and the cake packed like large Gloucester cheeses, or small grindstones in circular shape, is distributed throughout China in every direction both as food for pigs and buffaloes, as also for manure."

BEE-KEEPING.

Read the following note from Mr. John Douglas in continuation of the subject introduced at the last meeting:—

"I am exceedingly obliged by your letter of the 21st ultimo, granting me every facility for cultivating bees at the Society's Nursery Gardens, Alipore, and I hope to be able to avail myself of the facilities so obligingly offered at an early date.

"I am endeavouring to obtain swarms of the large native bee, particularly of *Apis dorsata*. I should feel greatly obliged by any assistance towards this object which any member of the Society may be pleased to afford.

"I may mention that Apiculturists in Europe are exceedingly anxious to obtain this bee for trial, and I have arranged to send a swarm to the British Bee-keepers' Association for trial.

"It may interest you to know that of two queens and three swarms of Italian bees, I have succeeded in saving two swarms, which are now breeding, and one queen."

From Dr. John Anderson, Superintendent, Indian Museum, applying for information regarding the keeping of bees by natives of this country.

The Secretary mentioned he had afforded such information as was possessed by the Society.

PROTECTION FROM WHITE-ANTS.

Mr. Marshall Woodrow, Superintendent, Botanical Gardens, Gunesh Khind, Poona, gives the following as an antidote for white-ants:—

"Perchloride of mercury, as its name implies, is a compound of chlorine and mercury. It is a heavy white crystalline substance soluble in water, and very poisonous. It is procurable from any chemist in a large way of business. This substance has been in use during many years among botanists and other naturalists to protect their specimens from insects, and recently has been tried with success against White-ants.

"To use the perchloride of mercury it should be dissolved in water and the papers to be preserved dipped in the solution. Glass or glazed-ware vessels only should be used to keep the solution. As some officers meet with a difficulty in getting this substance, a small quantity has been prepared at this office for distribution. It is packed in small packets, each sufficient for one quart bottle of water, and these packets are enclosed in a paper bearing directions for use and containing one dozen packets."

COMMUNICATIONS ON VARIOUS SUBJECTS.

1. From Captain Pogson, furnishing some information in respect to *Pyrethrum* as an insecticide:—

I see by the proceedings of the Society for September last, that information is desired on the subject of the *pyrethrum*, and I trust that given on the other page will suffice. The *pyrethrum* is much used as a bedding foliage plant, and does not grow much higher than 18 to 20 inches at Kotegurh. The *Chrysanthemum* is from 2½ to 4 feet in height at Simla and Kotegurh. The native name for the plant and flower, is "Gooldacodes," or David's rose.

There are five varieties of *pyrethrum*—one, 2 feet high, two of 3 inches each, and two of 8 inches each. These four are invaluable for bedding: all four are called "Golden feather," the old name being "Fever Few."

I should say a solution of carbolic acid, applied through an "atomizer" or spray-producer, would destroy the red-spider, and anything else in the insect line. It does so in America. Tobacco water may be similarly used.

No. 1, *Pyrethrum parthenium* (Linn). "Common Fever Few."—Flower of disk yellow, of the ray white. July. Perennial.

"The whole plant is bitter and strongly scented, reckoned tonic, stimulant, and anti-hysteria. It was once a popular remedy in ague: its odour is said to be particularly disagreeable to bees, and that these insects may be easily kept at a distance by carrying a handful of the flower heads."

No. 2, *Pyrethrum Tunacetum*.—"Leaves stomachic, cordial, cephalic, uterine; seeds vermifuge." Flowers not described. (South of Europe).

No. 1 grows perfectly in Simla and Kotegurh. The leaves are pale yellow with a greenish tinge. Flowers in July, August. Seeds freely. Won't answer in the plains. A foliage plant as well.

Chrysanthemum coronarium (Linn.). Garden chrysanthemum. South of Europe. Flowers used to discuss steatomatous tumours.

No. 2, *Chrysanthemum segetum*, (Linn). Corn chrysanthemum. Flowers yellow. June to August. Annual. Cornfields. Discussive and attenuant when used externally; and given against the jaundice, asthma, and shortness of breath.

2. From Under-Secretary, Government of India, Revenue and Agricultural Department, enquiring for information in respect to sand-binding plants. Compiled with.

3. From the same, forwarding a model of the "Mexican aloe fibre-extractor," referred to in the proceedings of the last meeting.

4. From Messrs. Balmer, Lawrie & Co., requesting full information in respect to the cultivation of the aloe plant. Compiled with.

5. From J. Clarke, Esq., Melbourne, acknowledging receipt, in fair condition, of a case of orchids in exchange for ferns.

SELECTIONS.

MR. ROBERTSON ON "TILLAGE AND PLOUGHS."

ON the evening of Wednesday, December 13th, a lecture was delivered in Bellary by Mr. W. R. Robertson, Agricultural Reporter to the Government of Madras, on "Tillage and Ploughs." Mr. H. P. Gordon, the Collector, was in the chair. The lecture was delivered in the large room of the Warlow Institution. There was a large attendance of the general public, including many landowners and ryots from the surrounding neighbourhood. Mr. Gordon, on taking the chair, pointed out that the presence of Mr. Robertson at Bellary was due to a desire on his part to

learn something, definitely, regarding the results of Mr. Sabapathy Mudaliar's great enterprise in introducing so extensively superior European ploughs into the district. After noticing generally the very creditable manner in which this new enterprise had been started, Mr. Gordon introduced the lecturer.

Mr. Robertson spoke as follows:—My visit to Bellary on this occasion is, as Mr. Gordon has stated, chiefly in connection with the agricultural reforms instituted by Mr. Sabapathy Mudaliar. I have come to see what Mr. Sabapathy Mudaliar has effected, and to learn how far his example is being imitated by others. It was thought that I might with advantage give a short lecture in this town on Tillage and Ploughs; these subjects being of special interest at present here. Before proceeding to refer to ploughs in detail, I shall first bring under your notice some general facts referring to tillage. And first, I would remark that you may till a soil without making use of a plough; indeed, strictly speaking, the soils of Southern India are not ploughed. The implement generally used by our ryots, which is called a plough, is really what is termed a cultivator, being without a mould-board for receiving and turning over the soil. Most persons are aware that the productiveness of land is greatly stimulated by the soil being stirred, loosened, and turned by tillage implements. Land that is left untilled produces only vegetation of a very low order. It is true that, on such land, trees are produced without the soil being tilled; but trees, generally, require several years, and some kinds many years, to reach maturity; while, as you know, most of our cultivated crops must be sown, grown and harvested within a period of less than half a year; it stands to reason that if the plant you desire to cultivate has a very short life, it is expedient that it should be maintained in the fullest possible vigor during its period of growth, in order that it may be fully developed and matured; and this development will depend very largely on the amount of available plant food within the reach of the roots of the plant. I must remind you that plants, like animals, need food, and that it is no more possible for the plant to live without food than it is for an animal to do so. Again, you must remember that animals possess the power of moving about to search for their food; while plants are fixed in the ground, and though, to a certain extent, they do spread their roots in search of food, this power is but limited. It is therefore highly necessary that you should place the food of plants in close contact with their roots. In referring to the food of plants, I should point out of what this consists. Soils are composed of various mineral and organic matters; the former are sand, clay, lime, potash, soda and several other substances. A good soil contains a fair proportion of all these, which are called the mineral constituents of the soil; the organic substances are composed chiefly of the remains of plants which have become partly decomposed. It has been ascertained by examining, by analysis, great numbers of samples of each variety of field produce, that crops differ in their demands on the food yielded by the soil. One variety of crop feeds largely on potash, and will not thrive in a soil in which there is a deficiency of this mineral; another variety of crop feeds largely on lime, and cannot thrive without lime in the soil; while another must have soda, and so on. You will readily understand that if a crop which feeds on the lime is grown continuously on a piece of land to which no lime manure is added, that crop must in time find less and less lime in the soil, and therefore the power of the crop to become fully developed is lessened year by year, until, eventually, if the cropping is continued, the soil will be unable to yield an outturn of the crop sufficient to repay the expenses of cultivation. When a soil has thus been reduced in the scale of fertility, it is said to be exhausted. Of course, it is not absolutely exhausted, for it may contain appreciable quantities of lime, and other mineral matters, but yet not in sufficient quantities to admit of a paying crop being produced. When land is in this state, it is usually abandoned by the ryot, and, after remaining uncultivated for a number of years, it is probably again resumed for cultivation, and, not unlikely, will, for some years again, yield such crops as will satisfy the ryot. The explanation of this restored fertility is, simply, that the soil has again replenished its store of available plant food; which was nearly all used up, when it became necessary to abandon the land. This new store of available plant food would have been derived from the store of inert, inactive, plant food, of which most soils contain a large quantity. You may exhaust a soil speedily of its readily prepared plant food; but the inert plant food is stored up safely against undue wastage, and only becomes available for use, either by the land being left for some years to the influences of the air, which gradually unlocks and sets free a sufficiency of plant food for the requirements of a further succession of crops. It is the special object of all tillage operations to open up these stores of plant food; the more deeply and thoroughly the soil being tilled, the greater the quantity of the plant food set free for the use of the crops to follow. It is very true that the more deeply and thoroughly you till your soil, the better you are able to take out of the soil, by means of your crops, the plant food the soil supplies; but in good farming the larger are the crops you produce, the greater must be your applications of manure. Remembering that you apply to the soil refuse matters which possess but a low money value, and which for sanitary reasons should be buried in the soil, and you gather, in your crops, produce which possesses a high money value. There are some soils so rich that they will grow good crops for a long series of years without having any aid from manure; but even with such soils, it is very unwise to crop them without manuring them; for, deterioration must take place when you are constantly taking from the soil and add nothing to it. Remember that so far I have been speaking chiefly of deep tillage, not deep ploughing. In deep ploughing you bring up to the surface of the land a portion of the under-soil, and if this has not previously been stirred by tillage implements, it may not immediately be fitted for the use of plants, or it may contain matters which are noxious to plants. In either case the surface

soil will, for a time, suffer injury. Again, if the sub-soil is poorer than the surface soil, and by deep ploughing you bring the sub-soil to the surface, you must by the admixture reduce the fertility of the surface soil. It is, however, but seldom that the sub-soil is poorer than the surface soil. In most cases the sub-soil is much richer than the soil, from the latter having been deteriorated under the effects of continuous cropping without the use of manure; while, owing to shallow tillage which prevails almost universally throughout Southern India, the sub-soil is generally almost virgin soil; requiring only to be deeply tilled to be made available at once for the growth of crops. When a soil has been injured by injudicious deep ploughing, in most cases the injurious effects last only for a year or two, as the soil under the influence of the atmosphere and the sun rapidly recovers from such injury, and the raw unprepared food thus prematurely brought to the top is cooked, as it were, and rendered fit for consumption by plants. The enoe between deep tillage, or cultivation, and deep ploughing consists in the former, in the soil being left in the same and merely stirred and moved; whereas, in deep ploughing, as I have before noticed, the fresh underneath soil is brought to the top. You may deeply till any soil without injury; indeed, with every advantage; but you can only deep plough with advantage under certain conditions; unless the deep ploughing is attained gradually, that is, say, one inch greater depth each year. There are soils that may be deeply ploughed at once with every advantage resulting. Much of your cotton soil may be deeply ploughed at once, because the sub-soils have been opened up, and have been aerated, through the agency of the long tap roots of your cotton plants. These, by penetrating the sub-soil deeply, have opened it up, and given access to air and water. Deep tillage, and deep ploughing, are beneficial, not only because these operations give the roots of your crops access to a much larger volume of soil, in which to feed, but the roots, by going deeper in the soil, are protected from the scorching influences of a hot sun; the plants growing on such a soil are during a draught much more luxuriant and robust than those growing on shallow-tilled or shallow-ploughed land. Besides, the plants on the deeply worked soil, having access to greater stores of plant food, are far more healthy, and better able to withstand the effects of disease. On well-worked deep soils, a larger porportion of the rain sinks into the soil than on shallow soils, and the deeply stirred soils becomes a reservoir for the storage of water. Again, in deeply worked soils, the watery vapour which, in the form of dew, and fog, frequently rests over the land, finds access in the soil, and is stored there. An acre of well stirred soil will always in the dry seasons contain many tons more of water than shallow badly tilled soils, and this, of course, in your climate, is a matter of considerable importance. Shallow tillage is to be condemned from every point of view in a climate such as this. It is perhaps fortunate for you, and those who are to come after, that shallow tillage has hitherto been the rule here, for it has preserved to you a large quantity of plant food in the subsoil, which, under other circumstances, might have been used up. From what I have said, you will understand that the soil is not an inert mass, but is subjected to great physical and chemical changes, the greater and more efficacious these are the better you till your soil. But I must now pass on to notice the second subject of my lecture—ploughs.

As I have already noticed, the so-called country plough is no plough at all, but a mere cultivator. But, for convenience and simplicity, I shall refer to it as the country plough. It is not confined to India, for a plough very similar is yet met with in several other countries; indeed, judging from the evidence afforded by Egyptian monumental tablets, and similar evidence in other countries it would appear that the so-called country plough was the plough used in every country at one period of its history, but, whereas other countries have abandoned the primitive plough, and adopted improved forms, you have, in this country, made no progress in this direction. The so-called European plough is, comparatively speaking, but a recent invention. In its low cost, at first sight, the so-called country plough seems to possess a considerable advantage over the various forms of improved ploughs. But let us consider whether this is so. You know that the country plough cuts a V-shaped furrow, and thus there is between each furrow made by the plough a rib of unploughed land. Under favourable conditions, a country plough will form a furrow 5 inches wide at the top and 2 inches wide at the bottom, the section of the furrow thus measuring 15 square inches. Ploughing such a furrow the plough must travel 20 miles to go over 1 acre of land; but, you must remember that one-half of the land to a depth of 5 inches is yet unploughed, and that to move this remainder, the plough must cross the whole of the land again, thus the plough must travel 40 miles, to plough 1 acre of land, and the soil, it must be remembered, is not even then efficiently turned. But, even supposing that, in two operations the country plough could stir the whole of the soil to a depth of 5 inches, we have this fact that only 672 cubic yards of earth would be moved. Now, I have said that the distance to be travelled must be 40 miles, which is equivalent to three days' work of a country plough. In other words, to move an acre of soil to a depth of 5 inches in a day, would give full employment to three country ploughs, three pairs of cattle, and three drivers, and the soil would be moved at a cost of 1 rupee per 400 cubic yards. An improved mould-board plough would, under average conditions, cut a furrow 9 inches wide and 7 inches deep, in a perfectly rectangular form, the whole of the soil being cleanly cut, raised, and turned over. The section of the furrow would thus measure 63 square inches, against 15 square inches, the area of the section of the country plough furrow. A fair day's work for such an improved plough would be 2 of an acre ploughed, and to effect this the cattle must travel eight miles, excluding turnings at the headlands, and the volume of earth lifted and turned over would be 705 cubic yards against 672 cubic yards moved by three country ploughs in a day. In other words, the improved

plough would, for one rupee, raise and turn over efficiently 321 cubic yards of earth; while, with a country plough for the same sum, you could move, and this very inefficiently, only 290 cubic yards of earth, but I need not press this point, for you in Ballary have given practical proof of your appreciation of these facts. I might occupy your attention for a long time in describing the different kinds of ploughs that are now made; but you would learn much more if you would pay a visit to Mr. Sabapathy Mudali's establishment in this town, where to-day I saw one of the

ploughs that I venture to believe has ever been got together in India. You must remember that the form of a plough has much to do with the force required to draw it through the ground. Many country ploughs, weighing only about 500 lb., require much force to be exerted by the cattle in drawing them, than similar cattle would need to exert in drawing improved ploughs of twice the weight. If you will examine the model I now hold of a country plough, you will see how imperfect is its construction, and yet it resembles hundreds of ploughs in constant use in this district and elsewhere. You see there is a large block, with a broad flat surface in front. Now of course you know that it takes more force to draw through the ground such a block than a wedge-shaped one, when a narrow edge is in front. You never see boats with square bows; the bows of the boat are more or less pointed in view to cut the water in the passage of the boat, and your plough should cut the soil like a wedge, if you would get the work performed with the least expenditure of the labour of your cattle. A sort of weighing machine is used for determining the exact force exerted by cattle in drawing ploughs, and other implements, through the soil. By means of this implement, which is called a dynamometer, we can tell exactly how much force the plough cattle must employ in pulling through the soil different kinds of ploughs. I have made many experiments with this little instrument, and it has shown me that many country ploughs are much more oppressive on the cattle drawing them than would be some kinds of improved mould-board ploughs. I have found country ploughs that showed that the cattle exercised a force as much as 400 lb.; while the same cattle, in doing better work with some kinds of improved ploughs, would not need to employ more than half this force. Many improved ploughs are made of iron with iron working parts, but I prefer ploughs made entirely of iron; as those partly of wood and partly of iron in this country do not last long. As a rule, malleable iron is to be preferred for making a plough to cast iron; but you must remember that cast iron is cheaper and that you can readily get in cast iron duplicate of the parts of your ploughs liable to wear out, at a small expense. Steel is preferable, especially malleable steel, to either cast iron or malleable iron, for the working parts of a plough-steel offers less resistance in the soil; being stronger than cast iron, or malleable iron, the weight of the plough can be reduced without sacrificing strength. It has been suggested that this district offers peculiar facilities for the introduction of steam-ploughing; and there cannot be a doubt but that the land, generally, is well circumstanced for steam-ploughing; that is, you have vast plains of land composed of soils that ought to be deeply ploughed; land without the obstacles met with in other countries, in the form of fenows, trees, rocks, &c. Until recently, the cost of fuel prohibited any possibility of steam-ploughing being attempted here; but the recent improvements in engines which have enabled steam to be raised by the use of refuse vegetable matters, such as indigo refuse, stalks of cotton plants, &c., has lessened greatly the fuel difficulty. The one great drawback that yet remains is the absence of good roads when you remember that a steam-ploughing engine weighs about eighteen tons, with its water and fuel, when ready for work, you will quite understand how impossible it would be at certain seasons to get such a ponderous machine moved about over your black cotton soils. As you will see from these diagrams, there are two great systems of steam-ploughing—the one called the round-about system, in which only one engine is used; and, the other the double engine system. You will notice that in the former, by an arrangement of ropes the plough is moved backwards and forwards across the field between the engine, and a windlass placed opposite each other. In the double-engine system, as you will see, the plough is pulled across the field by one engine, and pulled back by the other. This system is considered the best, as the engines are locomotive, and need no help from cattle, in getting with their apparatus, from field to field; whereas, in the first mentioned system, a great number of cattle are necessary to move the engine and apparatus from field to field. But both these systems of steam-ploughing will, I think, have to give place to the new steam-digger—a new implement which is now being experimented with in England. The steam-digger is rapidly coming into favor; it has been found to perform work even more efficiently than the steam-plough, and at the rate of as much as one acre per hour. This new apparatus needs no complicated rope system, for the digging apparatus is attached direct to the engine. The invention is yet of too recent a date to admit of one speaking with any degree of confidence as to its future. All that can, at present, be said is that the machine promises to be a success. At present however, it is offered at much too high a price—£1,000. I would advise great caution in introducing steam machinery; with the rapid progress we have seen of late, in adapting electricity as a motive power, we may reasonably hope ere long to have this new motive power competing closely with steam even in the tillage of the soil.

On Mr. Robertson resuming his seat, Mr. Sabapathy Iyer, barrister-at-law, rose and addressed the meeting in Canarese, repeating the substance of the lecture in that language, for the benefit of the ryots in attendance who were not acquainted with English. He was listened to with great attention by a highly appreciative audience who, by their expressions, appeared fully to understand the special points of interest to which Mr. Sabapathy Iyer called their attention. —*Madras Mail*.

INDIAN TEA.

IT is remarkable that whilst Tea is so universally used in England the public should know so little about it, and be, therefore, such indifferent judges as to what they should look for as the signs of a good article. There is a mistaken notion still abroad that "flowery Pekoe" is made of the white, camellia-like blossom from the bush, and that several species are cultivated to produce the various qualities of Teas. Many of your readers may feel an interest in learning something concerning the Kangra Valley Tea district and the method of cultivation, picking, and making of the Tea there grown. The exhausted leaves from their tea-pots will then guide them in their future purchases; when they have learned that in carefully made and honestly packed Tea there are no sticks or other incongruous matter, but simply the leaf of the curled, dried Tea, which has been opened and expanded in the water to something like its pristine state.

All the kinds of Tea, which are described as Pekoe, Orange Pekoe, Pekoe Souchong, &c., are picked at the same moment, from the same stem, from the same bush. The barely developed little leaf, covered with a delicate down, which is just unfolding on the top of the spray, is to produce the finest Tea; the first perfect, but still tender leaves, the next; and the broader ones, lower down, the Bohos, or coarse Tea. These leaves are all manufactured together into Tea, as we shall see presently; and the best Tea to drink is, perhaps, the liquor derived from the mass as it stands. But the different sized leaves are all laboriously sorted by hand, after manufacture, before they are exported to the English market, to meet the requirements of the trade and in accordance with the China mode. These carefully sorted leaves have to be mixed again to make a Tea for actual use, such, for example, as Pekoe Souchong, which is, perhaps, the best mixture; and some of the finest Tea goes to make coarse China Teas drinkable and fit for the market. The coarse Teas from the Kangra Valley are sold in India and are not exported to England, where we get the mass of our Tea concentrated, as it were, by this removal of all leaves of scanty strength and flavour.

THE KANGRA TEA PLANTATIONS.

These lie along the slopes of the North-West Himalayas, nestling at the feet of grand mountains of from 10,000 to 16,000 feet high, and comprising, between the Ravee and the Sutlej, 8,000 square miles of country. The district of Kangra proper, leaving out the sub-division of Kulu, and the highly picturesque native states of Mundi, Sooket, and Chumha, extends from the Beas, where the natural watershed divides it from the Hoshiarpore district, to the boundary of the Mundi State, near Rijnath, on the one side, and to Noorpoor on the other. It is in this lovely valley that most of the European Tea-planters have settled, and made around them comfortable homes and homesteads, which remind the sun-scorched visitor from the plains of India of far-off English farms.

At the upper part of the valley, and lying opposite to a huge gorge in the mountains, from which the planters obtain their daily supply of ice in the summer, lies Palampur, the head-quarter station of the Tea district, with its Government offices, rest-house, dispensary, planters' club, and beautiful little church. Palampur, which is 4,000 feet above the sea-level, enjoys an excellent climate for eight or nine months in the year; during the other months the heat and rains are somewhat disagreeable, although admirably adapted to the growth of Tea. The beautiful little station is situated on a series of gently sloping knolls of green turf, thickly studded with Cheel trees (*Pinus longifolia*), and has the universal Kangra background of mighty mountains. The place is greatly indebted to the exertions of Sir Douglas Forsyth, who did a great deal for it and its immediate neighbourhood whilst he was the Commissioner of the district. His attempt to establish an annual fair at Palampur, to induce traders from Yarkand and other distant provinces of Central Asia to open up trade with British India, is a matter of history; and the causes of its failure are written in the records of the diplomatic offices of England and Russia.

When land has been selected and purchased (no easy task in a district where by a mistake in the settlement a great portion of the waste, or uncultivated lands suitable for Tea were given to the natives, and where the bargains have for the most part to be made with the wily intriguing Hindoos), and whilst it is being cleared of jungle and prepared for a Tea garden, the seed for the future plantations must be sown. The original seed which was used in the district was introduced by Dr. Jameson, the official Government pioneer of Tea cultivation, who selected Kotla, Bawarrah, and Negreta as gardens, and sowed that seed which he had brought from the Dehra Doon, and which became so reproductive in the soil of the Kangra Valley that it now supplies the planters of its native Doon, and many of the younger Tea districts. H. H. the Maharaja of Cashmere has of late been a large purchaser of seed, for, not content with energetically pushing on the growth of vines and hops, his Highness seems bent at the same time on producing something with which his people may cheer themselves and escape inebriation.

The seed is carefully removed from all Tea bushes in the garden during October and November by boys, girls, and women. A large yield of seed is an indication of something wrong in cultivation, or season, or soil. The planter's object is to grow as much new, vigorous leaf as possible, and cultivation suited to leaf production is not productive of an abundance of seed or fruit; and, therefore, all that advertising dealers and brokers tell the public about flower and seed is simple nonsense to those who understand the business, and have ever seen Tea grown and made.

The ripe seed, which is picked in the autumn, has not shed its outer husk, and is sown entire as it comes from the bush in neatly made nursery drills a foot apart and 4 inches deep, a shaded spot being selected for the seed bed that it may be protected from the

cold of winter and the parching heat of the full summer's sun. As the necessary decay of the seed takes place in germination, the outer husk decays and feeds the young plant. Although this care is necessary in raising seedlings in the comparatively temperate climate of Kangra, the hot steaming climate of Assam, where Tea is indigenous, produces all vegetation in such luxuriance that the seed has but to be dibbled into the land which it is permanently to occupy like a row of beans.

CULTIVATION.

The periodical rains commence in the Kangra district on or about June 15, and, if they be not too heavy, the seedlings may be transplanted to their places in the garden at the beginning of July. For this planting out, arrangements will have been made during the winter months. In rich soils, where the growth of the bushes will be quick and luxuriant, the seedlings are put in at greater distance from each other than in poorer soils, where the bushes will be longer in approaching each other. According to soil, these pits, 2½ feet deep by 1½ foot wide, are dug in rows varying from 5 feet by 5 feet in good soil, to 3 feet by 4 feet in poor soil, and into each of these pits from ten to twelve seedlings are planted. The coolies who put them in are drilled by a jemadar, or headman; who takes his place and orders from the planter himself; and so well is the work done in this way that the plants are rarely an inch out of the direct line, or of the proper depth in the soil. Under the magic wand of English energy, what was but now virgin soil of the forest or the village common, or the arable land of the natives, is a young Tea plantation, not yet ready to be plucked, but growing wondrously fast, needing to be carefully terraced to keep the soil up, if it be on a slope, and to be sometimes irrigated in hot, dry weather. In three years the plants in good soil begin to be profitable, and need no further waterings, although they are not in full bearing for, perhaps, seven or eight years.

During their minority each plant requires careful cultivation, constant hoeing, fairly liberal manuring, and judicious pruning. In November the winter cultivation of the mature bushes begins. Divisions of men—the strongest and possibly the least intelligent—are told off to hoe the garden throughout 1 foot deep; and this hoeing work should go on all the year round with variations at different seasons of the depth of hoeing.

PRUNING.

Simultaneously with the hoeing, so that all that is cut off the bushes may go back and be buried in the soil, the pruning commences. As pruning is one of the most important works on a plantation, so is it one on which there is the greatest difference of opinion. A great many experiments have been made in the art, and probably planters have not yet learned all the science of the subject. Ten years ago an indiscriminate slashing off of the top of the bush and cutting three or four large holes into the body of the plant, to let in light and air, was the style of pruning most in vogue, chiefly on account of its fancied economy. By this method of pruning numberless shoots no doubt sprung up in the spring, but from the very fact of their being so numerous the bush was choked up as to all after-growth, and became a mass of unproductive crow's-foot.

Thorn pruning was next tried, and it may answer admirably in a cold climate, but certainly it is not the proper method for shrubs in high temperature, such as Tea requires, for they need protection from the sun and from electric and winter hail, without which the wood branches and the sap dries.

Coppicing, as a last remedy for old woody plants, was then tried; but the remedy is a most severe one; the plant loses much strength by the inevitable bleeding which takes place, and consequently the new shoots it makes are weak and feeble.

A new method of pruning which has been introduced into the valley is at present the approved one. The old, white, gnarled wood, and all the "whip-cord," is cut off entirely an inch or two below the surface of the soil in such a way as shall cause the bush to bleed as little as possible. Then all the long, straggling shoots are cut back, no matter how good their material may be; and lastly, all the shoots are cut back close to the finest bud growing from the axilla of the leaf, which is left to act as shelter.

Bushes of about 4 feet in height are the most convenient for boys and girls to pick from, and some of the finest bushes in the Kangra Valley gardens are of this height, and 6 or 7 feet in diameter.

Pruning operations are going on from November to the end of the first week in March. Boys in India are almost always sharper and more active and willing than men. Strong, picked men cut out the thick, tough wood from beneath the soil, and the lighter pruning is done by the boys. The best pruner cannot average more than twenty full-grown bushes in a day.

(To be continued)

A POULTRY FARM.

THE following account of a poultry farm forms a part of the report on Huntingdonshire, which, as an Assistant Commissioner, was written by Mr. Druce for the Royal Commission on Agriculture. The paper, with a note appended, appeared in the *Journal of the Royal Agricultural Society of England*.

The farmers in Huntingdonshire have endeavoured to meet the bad times as well as they could; and among other attempts that have been made, one of them has tried poultry farming on a somewhat large scale. The farmer who has tried this lives at Kimbolton, and up to a year or so ago he farmed a good-sized farm of between 500 and 600 acres; but finding things were going badly, he gave up the larger farm and retained one of about 100 acres only, and it is upon this that he is trying poultry farming. The soil of the farm is a tolerable stiff clay, and most of it is already, or will very soon be, drained. It is farmed pretty

much on the four-course system, and the poultry is the chief live-stock kept upon it.

The farmer had kept poultry in some numbers for the past five or six years, whilst he held his larger occupation; but he had not kept a separate and distinct account relating to them till the year 1880, and since he had given up that occupation. He stated that he was trying the system because of the very large importations of poultry and eggs into this country, and because he thought that poultry, if properly attended to and treated in a business-like way, would pay. He kept fowls only, not ducks, geese, or turkeys. He had tried various breeds of fowls, but preferred the light Brahmas to all others, because from experience he had found that breed to be the hardiest and most prolific. His stock at the time of my visit (October 1881) consisted of about 1,800 head, which in the winter would be reduced by some 300 or 400, so that at that period of the year he would have about 1,400 or 1,500. He keeps no old stock, but sells all his birds before or when they are two years old. He is careful to have fresh blood in his stock every year, and for that purpose periodically introduces three or four male birds of some other strain than his own of the light Brahmas breed. His stock has always been healthy, and absolutely free from any epidemic during the six years that he has kept it, and though he has occasionally lost a few birds, his losses from disease have been very trifling. He keeps the poultry partly in yards at the farm homestead and partly in the fields. There are nine yards at the homestead of different sizes for convenience sake, and separated from each other by wire netting; and attached to or near them are houses for the fowls, such houses being parts of the farm buildings adapted for that purpose. The fowls in the fields are divided into different lots, each lot containing about 150 birds, and having a separate fowl-house: these houses are about 16 feet long by 8 feet wide, and 6 feet high up to the eaves of the roof, and contain from 750 to 800 cubic feet each, or rather more than 5 cubic feet to a bird. They are built of wood, and are moved from one part of a field to another very easily by one horse. The field houses, when I saw them, were on a piece of land that had been laid down to grass about two or three years ago; and just previously they had been on some young seeds sown in a barley crop which had not long been harvested. As soon as the ground near the house has become much trodden, the house is removed to some other spot. These removals take place about every fortnight. The yards at the homesteads are changed once a year, and the ground which has been used as a yard is left for a year without any fowls being put upon it, in order that it may become sweet, and freed from the taint of the birds. All the houses are scrupulously clean, and are constantly lime-washed. The birds, except the young chickens, are fed three times a day; in the morning with salt food, consisting of boiled potatoes, mangels, carrots, or parsnips, mixed with barley flour, which mixture is given warm in the winter; in the middle of the day they are fed with inferior corn; and at night with a full feed of sound maize—the best description of that corn only being used, and it is given to the fowls whole, and not split. No particular quantity of food is given at either meal, but notice is taken whether any of that which is given is not picked up, and if such is the case, less is given. Occasionally the fowls have green food, and in the winter meat. The meat is boiled horseflesh or beef, and care is taken that the meat is that of a sound animal, and of an animal that has been killed, and not of one that has died of natural death. The chickens are fed as often as six times a day, with all sorts of food, and are most carefully looked after by the man in charge and his boy, who are the only labourers employed for the poultry. The manure made by the fowls is used on the farm as a top-dressing for corn, and is mixed with malt dust or kiln dust, which is spread over the floors of the houses, and absorbs the manure when it is dropped. In this way the houses are more effectively cleaned out, and the manure so mixed is found to be very efficacious. The poultry and eggs are for the most part sold for consumption in London, but occasionally a few of each are sold locally. The following is a statement of the receipts from, and expenditure upon, the poultry for the year 1880:—

| RECEIPTS. | | £. | s. | d. |
|-------------------------------------|-----|------|----|----|
| For eggs and poultry sold in London | ... | 433 | 10 | 10 |
| " " to house | ... | 16 | 1 | 0 |
| " " to Dowden | ... | 2 | 10 | 0 |
| " " to others | ... | 9 | 10 | 0 |
| For manure | ... | 27 | 0 | 0 |
| " feathers | ... | 3 | 0 | 0 |
| | | £491 | 11 | 10 |

| EXPENDITURE. | | £. | s. | d. |
|--------------------------|-----|------|----|----|
| Paid for food | ... | 330 | 0 | 0 |
| " labour | ... | 55 | 6 | 9 |
| " eggs | ... | 10 | 0 | 0 |
| " rent | ... | 33 | 0 | 0 |
| Depreciation and renewal | ... | 18 | 10 | 0 |
| Interest | ... | 15 | 0 | 0 |
| Balance (profit)... | ... | 25 | 1 | 10 |
| | | £491 | 11 | 10 |

The capital employed in the poultry farm was taken at £200, and was considered as being the same at the beginning and at the end of the year, and interest at 5 per cent on that amount is allowed in the foregoing account; there was, however, in fact, rather a larger head of poultry at the end than at the beginning of the year, the actual numbers being on January 1, 1880—1,433; on January 1, 1881—1,492; but the difference

in number was not sufficient to make any material difference in the value. Of the £200 capital, £200 was taken as the value of the poultry, and £100 as the value of the fowl-houses and other dead-stock; the former sum seemed to be very inadequate, and, upon consideration, the farmer added this note to the above note:—"I have charged 5 per cent interest on £300—viz., £150 for houses—though I consider my fowls, hmas of noted strains, are worth £400." If, then, we take the whole capital in the concern at £400 (the mean between the capital of £200, on which interest is calculated in the above account, and £600, the amount at which, upon further consideration, the farmer estimated it), which would, as far as I could make out, fairly represent actual capital invested in the concern, we find that a return of some £40, or 10 per cent was made, the £40 being divided in the account into £15 for interest and £25 for profit; but if we take the capital at £400, and allow interest at 5 per cent on that sum, we have only £20, or 5 per cent, left for profit.

This farm seems to be a fair example of what can be done by poultry farming, for there are no special or adventitious circumstances as regards soil, position, or otherwise connected with it, but the farmer thoroughly understands the business; he is learned in poultry, and devotes much of his time to them. He is not only fond of poultry, but of other animals, as is shown by the fact that he keeps a large number of bees on the most approved modern and scientific principles, from which he endeavours to make a profit. I cannot, however, state whether his bee-keeping has been profitable, for he has only kept them in large numbers during the past year, and has not kept separate accounts for them. I need hardly add that this poultry and bee farmer does not depend upon his poultry and bees, and his small farm alone for a livelihood. In reply to my question whether he thought that poultry farming on a very large scale would pay, he said he thought not; but that the best and most paying way to keep poultry was for the cottagers to keep a few each for their farmers, the cottagers' wives being paid so much per head for every chicken reared.

Before sending the foregoing description to the Society, for publication in its *Journal*, I wrote to the farmer whose poultry farm I have described, to ask him for a copy of his balance sheet for the year 1881, in order that the description might be brought down to as late a date as possible. In reply to my letter the farmer wrote as follows:—

"I have been trying to get out a balance sheet of my poultry farm for the year 1881, but find I cannot get at all the details, owing to their being mixed with the other business transactions; but I am satisfied, were I able to do so, they would not be found more satisfactory than those I gave you, in a financial point of view; in fact, my impression is such that I intend much reducing my stock and breeding for fancy sale only, feeling assured that breeding for the market cannot be made to pay on a large scale. I much regret being unable to comply with your request."

This letter would appear to show that the longer experiment had convinced the farmer of the correctness of the opinion he expressed to me,—namely, that poultry farming on a very large scale would not pay.

THE LIQUID-AMBAR, OR SWEET GUM.

THERE seems to have been great diversity of opinion amongst the older botanists as to the natural affinities of this genus. Some included it in a large and incongruous order, including all those trees with catkins as oaks, beeches, willows, and planes. Some made it an order by itself, called Balsamaceae; more recent authorities, however, class it with the witch hazels of North America. The catkins of the female flowers are globose, and resemble those of the *Platanus* externally. The trees themselves that are hardy in this country are much like Maples. Apparently only three species are known, inhabiting the warmer parts of North America, Asia Minor, and the South of Asia, especially Java.

Liquid-ambar *styraciflua* is the best known species in this country and the most ornamental. It inhabits the United States, extending southwards into Mexico, where it attains its maximum dimensions in swampy or wet places near rivers. Thirty or forty feet is the average height of the tree in this country, but if planted in a sheltered, moist place, it attains the height of 60 or 80 feet. It grows slowly, and with a little attention can be kept in pyramidal shape, forming at once a highly ornamental and interesting tree for the lawn or pleasure-ground; or if planted near the margin of large ponds, or on islets on ornamental water, it could not fail to be productive of the most pleasing effects. The leaves are acutely five-lobed, and serrated with woolly tufts at the junction of the veins beneath. They have a dark green leathery appearance, and when ripening in autumn become a blaze of deep purplish-red and orange. The bark is corky and fissured, but at a little distance is hidden by the dense foliage. Beneath the bark all parts of the tree are pervaded by a resin of a sweet balsamic fragrance. This substance is most highly developed in warm countries, and exudes spontaneously from any wound in the bark. It is of a clear or amber transparent colour, whence the generic name of the tree from "*liquidum*," fluid, and "*ambar*," amber.

The best is obtained by purposely making incisions in the bark, and a second-rate quality by boiling the bark and branches, when the oily material floats on the surface and is skimmed off. Another mode of obtaining it is by putting the inner bark in a bag and submitting it to pressure. This substance is used medicinally in several countries, and to a small extent in this. It is supposed to possess healing and balsamic properties, and in some degree to be stimulating and expectorant; while an oil extracted from the same substance is used in perfumery. The heartwood of the tree is dark, with a beautiful compact grain; and

furniture made of it has a handsome appearance. The product of this, as well as the following tree, has superseded the storax of the ancients, which was obtained from *Styrax officinale*, a low tree inhabiting South Europe.

L. imberbe, otherwise known as *L. orientale*, a low tree inhabiting Asia Minor, seldom exceeds 6 feet in height in England. It bears considerable resemblance to *Acer Campestre*, the common small-leaved Maple. The leaves are much smaller than those of *L. styraciflua*, with shorter, blunter lobes, and glabrous beneath; hence the specific name "*imberbe*," beardless. As an ornamental tree it is much inferior to the North American one, but interesting on account of its relationship. Although presenting the appearance only of a bush in tree form it is worthy of a place amongst other deciduous subjects, or as an isolated specimen on grass where a large tree would be inadmissible. Its economic uses are the same as that of the former tree.

L. altingia is a noble tree, inhabiting the forests of the West of Java, where it attains the height of 200 feet, and is found at elevations of 2,000 or 3,000 feet. The wood is reddish, and afterwards brown, of a beautiful compact grain, and, like its congeners, redolent of a grateful balsamic odour. The leaves are ovate-oblong, acuminate and serrate, quite a different type from the other species. As might be expected, it is not hardy in this country.

L. chinensis, sometimes seen planted against a wall in the open air, appears to be synonymous with this species. In severe winters it gets killed to the ground.

The hardy species are propagated by layers, or imported seeds—preferably the latter, because trees produced from layers seldom or never make such handsome specimens as those from seed.

—Observer.

THE PROSPECTS OF INDIAN TEA.

THESE are bad times for people who are personally interested in the well-being of tea estates in India, and there is no prospect at present of a change for the better. Cultivators cannot reasonably count upon an uninterrupted succession either of good crops, or of good prices; they must have their "downs" as well as their "ups"; they must have their bad as well as their good years. But the drop in prices of 25 per cent and upwards, that is shown by a comparison of present quotations with those ruling in London a year ago, is a disaster that the shrewdest planter may be excused for not foreseeing. Such a drop may mean something near to ruin to planters with small capitals or with many debts. By such as these money was wanted to open out ground, and the money was obtained from bankers at rates of interest regulated by the knowledge of the riskiness of the venture. The prices now realised for crop will probably not leave a surplus to meet the periodical payment of interest. Retrenchment in expenditure on the preparation of teas will be forced on the planters whose financial position is precarious, and such retrenchment means a lowering of quality. Already is the complaint made in London that the Indian teas are not as good as they used to be. In a falling and depressed market dealers are inclined to be hypercritical, or to discover, and make much of defects that they say nothing about when the market is firm. The London market is glutted with Indian tea, and is consequently in an irritable, bilious mood. "The supply of low-class Indian tea," says one London circular, "has largely increased of late, recent invoices containing a heavy proportion of Pekoe Souchong and Broken tea, with a general falling off in quality compared with earlier shipments, especially in Assam teas." It is also said that "last season owing to the general excellence of the crop the low grades had very superior liquors, while this season, although attractive in leaf, they are somewhat deficient in strength and flavour, the natural result perhaps of larger crops, and consequent lower standard of quality." We doubt, however, whether the planters have been so blind to their own interest as to be seriously inattentive to quality, while they have striven to increase quantity; and we doubt also whether the leaf of 1882 is markedly different from the leaf of 1881. While the latter went to a good, the former has gone to a bad, market, and does not perhaps have full justice done to it.

The London market cannot easily absorb the quantity of tea that now reaches it from India and China. In 1871 the exports of tea from India to all ports were 12½ millions of pounds, valued at £1,139,703; in 1881 they were 38½ millions of pounds, valued at £3,072,244. The consumption of Indian tea has increased necessarily in the ten years; but during that time China has largely increased her export, and it is commonly said in London that the supply of tea of one sort or another is in excess of the world's demand. From January to November, both inclusive, in 1880 the imports of Indian tea in London were 38 millions of pounds; in the same months of 1882 they were 48½ millions of pounds. The imports of China tea were 18½ millions of pounds in 1880, and in 1882 they amounted to 148½ millions of pounds. So the total imports of Indian and China tea were 196½ millions of pounds in the first eleven months of 1882, as compared with 177½ millions of pounds during the corresponding months of 1880. Taking the twelve months, January to December, and we find that the imports of tea from all ports into the United Kingdom amounted to 128 millions of pounds in 1867; to 141 millions of pounds in 1871; to 185 millions of pounds in 1876; and to close upon 210 millions of pounds in 1871, thus showing the enormous increase of 82 millions of pounds in fifteen years. The quantity retained for Home consumption in the United Kingdom was 111 millions of pounds in 1867, and 180 millions of pounds in 1881, showing an increase of nearly 50 per cent. In the fifteen years, during which the population increased from 35½ to 39½ millions, or by about 14 per cent. The stock of tea in London on the 1st December 1882 was 22 millions of pounds heavier than on the

same date in 1880. The pressure of this undesired addition to a stock that was supposed to be ample in 1880 has naturally sent down prices, and to some extent stimulated consumption; but not to the extent naturally desired by planters and shippers. The British public is still but little acquainted with Indian tea. There are a few shops in London which make a boast of selling their own "blends" of Indian and China tea, and at two or three places none but Indian tea is sold. But, generally speaking, the fact that more than a fourth of the tea consumed in England was grown in India is not known. The China teas have fallen off so much in quality of late years, or such large quantities of comparatively speaking "rubbish" have been shipped from China, that the chief use to which Indian teas are put is that of supplying the deficiencies of the China produce. A low quality and large quantity of China tea mixed with a high quality and small quantity of Indian tea results in a merchantable article, that is consumed by persons who do not dream that India has given the flavour that they find palatable in "the cup that cheers but not inebriates" them.

In the following table showing the prices current in London on the 7th December of Indian teas (for which we are indebted to Messrs. W., J., and H. Thompson's circular,) it will be observed that high prices in 1879 were followed by very low prices in 1880, and that high prices in 1881 were succeeded by low prices in 1882. Possibly, then, it will be the turn of 1883 to see prices that will gratify the planter, and recoup him for the disappointment he is now enduring:—

| | 1879. | | 1880. | | 1881. | | 1882. | | |
|----------------|-------|-----|-------|-----|-------|----|-------|-----|---|
| | s. | d. | s. | d. | s. | d. | s. | d. | |
| Duff | 0 | 11 | 0 | 7½ | 0 | 8 | 0 | 5 | Pale brown to black |
| FAN-JONG | 0 | 11½ | 0 | 7½ | 0 | 9 | 0 | 6½ | Pale chaffy to brownish |
| BROKEN TEA | 1 | 1 | 0 | 8½ | 0 | 10 | 0 | 8 | Darkish, leafy |
| BROKEN PEKON | 1 | 1½ | 0 | 9 | 1 | 0½ | 0 | 8½ | Darkish mixed broken Souehong leaf |
| COGNOV | 1 | 5 | 0 | 10 | 1 | 3 | 0 | 10 | Black and more even leaf, strong and fine |
| SOUCHONG | 1 | 4 | 0 | 10½ | 1 | 4 | 0 | 11 | Small blackish leaf with tips |
| PEKON SOUCHONG | 1 | 8 | 0 | 9 | 1 | 9 | 0 | 10 | Even leaf, with tips, strong and full |
| PEKON | 1 | 0½ | 0 | 9½ | 1 | 0 | 0 | 9½ | Roundish twisted leaf |
| | 1 | 1 | 0 | 9½ | 1 | 0½ | 0 | 9½ | Even leaf, with quality |
| | 1 | 2 | 0 | 10 | 1 | 1½ | 0 | 8½ | Coarse open leaf to good medium |
| | 1 | 3 | 0 | 10½ | 1 | 3 | 0 | 10 | Well made leaf, strong and full |
| | 1 | 3 | 0 | 10 | 1 | 2 | 0 | 9 | Even well made leaf, but weak... |
| | 1 | 5 | 0 | 11½ | 1 | 4 | 0 | 11 | Well twisted leaf, good strength and flavour. |
| | 1 | 4 | 0 | 11 | 1 | 3½ | 0 | 11½ | Common coarse leaf, and low quality |
| | 1 | 6 | 0 | 15 | 1 | 5½ | 0 | 13 | Well made leaf, with tips, fair quality |
| | 1 | 9 | 0 | 17 | 1 | 7 | 0 | 14 | Even wiry leaf, full and strong |

Though we decline to endorse the implied imputations of London dealers on tea-planters in India, we do not forget, nor should the planters themselves forget, that two years ago the Government of Sir Ashley Eden went out of their way to inculcate in a paternal manner upon the planters of Assam the extreme importance of conserving, by conscientious manipulation after careful cultivation, the high prestige of India tea. There are at the present time 171,193 acres under tea in Bengal, 10,174 acres in the

Punjab, 170 in Burmah, and 40,000 acres in Madras, or 185,537 acres in all British India. Given good prices and a steady market, and India, with a cultivated area of 136 millions of acres, may easily spare at least 400,000 acres, or an area equivalent to that occupied by tobacco, for the production of tea. The export of tea from China increases every year; but the proportion of really good to unquestionably inferior tea that she ships is steadily declining. Were the mandarins wise they would exercise a pressure, gentle or otherwise, upon their countrymen in tea districts, in order to bring home to them the fact that "lie" tea must in the long run be ruinous to those who to make it, and that apart from all moral considerations "honesty is the best policy." India is strong in high-class teas, and her planters should spare no pains to maintain the repute of those teas in European, American, and Colonial markets.

DIVI-DIVI.

THE cultivation of casuarinas has been of great pecuniary benefit to many persons in Madras, but it is only for timber that they are grown. Our attention has recently been called to the fact that there is a very good opening in this Presidency for the cultivation of the Divi-Divi tree, known in America as the Sumach, and botanically as the *Casualpina coriaria*, which produces not only timber, but what is more valuable, seed-pods, which realise a high price. It may be grown, too, as an ornamental tree. Some correspondence has appeared in our columns during the past few days, from which it appears that, though known to a few agriculturists in the Presidency, the advantages of growing it are not generally known, nor does it appear to have been cultivated to any great extent. It was introduced into India about the year 1839, and has been thoroughly acclimatised in South India, which, in soil and climate, resembles its original home. The largest plantation of Divi-Divi we have seen is that on the premises of Mr. J. B. Cardozo at Perambore, and before dealing with the subject generally, we will relate Mr. Cardozo's experience. Some twenty-five years ago two trees were planted in front of Mr. Cardozo's house, and flourished. A few years ago the value of the seed-pods for making ink was discovered, and Mr. Cardozo made enquiries which resulted in his sending seven bags of seed-pods to the London market in 1878, as a sample parcel. The brokers wrote with regard to it that "it is good and bold, and this quality will always command a ready sale at 13s. to 14s. per cwt. in large quantities, as far as can be judged at present." The parcel realised 13s. 9d. per cwt., and after paying all expenses, Mr. Cardozo realised a clear profit of about Rs. 9 per tree. Finding that the seed-pods were useful for dyeing and tanning, as well as making ink, Mr. Cardozo planted out a large number of trees, and he has now a plantation of about 600 trees. The manufacture of ink from Mr. Cardozo's seed-pods was extended, and a native of Madras has succeeded in obtaining a contract to supply the Government of India with ink powder for all the local Governments, the principal ingredient being obtained from Mr. Cardozo's seed-pods. The trees we specially refer to grow in what appears to be a clay loam of alluvial origin. The Divi-Divi generally grows well in a sandy loam. A sample of Divi-Divi pods grown on such a soil was recently analysed in Madras, and contained, in the marketable form, 27 per cent of tannin. Dr. Balfour states that the experiments made by Mr. Rootsey, of Bristol, showed the pods to contain 50 per cent of tannin, and that it is largely used by curriers. He also mentions that "the seed-pods on this tree being known to contain a large percentage of astringent matter, induced Dr. Cornish to use them in fever." The tree grows where the babool will, but does not like standing water. Mr. Cardozo believes that some of his trees which are shaded have grown better than those which have been exposed to the sun, but we do not think the tree really needs shade. In a Government circular published some time ago, we notice that it is recommended that the tree should be put down six feet apart, so that an acre of land will contain 1,210 trees, but this is surely a mistake, as the older trees at Perambore are 22 feet apart, and are already interlaced to the extent of six or seven feet. This would be prevented, of course, by pruning. The tree soon bears seed-pods, those at four years old bearing a large number: some branches producing so many indeed as to be unable to support them in a breeze. We should be inclined to plant it in lines in the same way as the Corkapilly—*Inga dulcis*—is planted for forming hedges, but at wider intervals; to be pruned but not clipped. Irrigation is necessary as long as the trees are not sufficiently grown up to dispense with it. The pods, and seeds contained, are usually sold together, and not the seed alone, as some writers seem to imagine. There has hitherto been very little trade in Divi-Divi pods in Madras, the exports during the past lustrum being as follows:—

| | | | | | |
|---------|-----|-----|----------------|-----|---------|
| 1877-78 | ... | 165 | cwt. valued at | ... | Rs. 660 |
| 1878-79 | ... | 15 | " | " | 73 |
| 1879-80 | ... | 169 | " | " | 590 |
| 1880-81 | ... | 150 | " | " | 633 |
| 1881-82 | ... | 133 | " | " | 621 |

We have noticed a few trees in some of the public places in Madras, such as the Napier Park, but doubt whether the produce has been gathered and sold. The Government have the subject under consideration, and we may soon hear of steps being taken to encourage the growth of the tree in this Presidency. We should certainly recommend a thorough enquiry into the matter, as the cultivation of Divi-Divi involves but little expense and trouble, and many an acre of land now producing nothing, or but very little, could probably be converted into a flourishing plantation. At any rate, the experiment is well worthy of a trial. The trees which have been planted on the site of an old manure heap at Perambore appear to have grown much better than the rest, and those who can afford to apply manure will probably find it profitable to do so. Divi-Divi is attracting attention in other countries we see. In the report on the Public and Botanical Gardens, Jamaica,

for 1881, we notice mention is made of "a piece of good land of about 2 acres in extent which has been enclosed with a hedge of limes and laid out in beds for raising the most important economic plants. The number of these plants ready for distribution amount to 32,000, and among them are Liberian Coffee, Nutmeg, East Indian Mangoes, Pimento, Oranges, French Limes, Casuarina, Janipur Cedar, Kola-nuts, Teak, *Bala immortelle*, Divi-Divi, Madras Thorn," &c. The tree is described in the *Treasury of Botany* :—

"*C. Coriaria* is a small tree twenty or thirty feet high, native of several of the West Indian Islands, Mexico, Venezuela, and North Brazil. The primary divisions of its leaves vary from nine to fifteen, each bearing from sixteen to twenty-four narrow oblong blunt leaflets, marked with black dots on the under surface. It has branched racemes of white flowers, which produce curiously flattened pods, about two inches long by three-fourths broad, and curved so as to bear some resemblance to the letter S. The large percentage of tannin in these pods renders them exceedingly valuable for tanning purposes. They are known in commerce under the names of Divi-divi, Libi-divi, or Livi-dibi, and are chiefly imported from Maracaibo, Paraiaba, and St. Domingo."

In Day's *Gardener's Dictionary* vol. II., p. 432, the 4th section of *Casalpinia* is given as *Libidibia*, from *Libidibi*, the name of the pod of this plant in Curaçoa, the *Casalpinia coarctata* of Willdenow, which is a native of Curaçoa, Carthage, and St. Domingo, in salt marshes by the sea-side. The legumes of this plant are called Libi-Dibi and are used in tanning leather when ripe by the Spaniards and natives. The tree grows 15 to 20 feet.

In the Bombay Flora of Danzell and Gibson published in 1861, this plant is noticed as follows :—

Casalpinia coriaria, Libi-Divi Native of South America.—A spreading, umbrageous tree; not high; leaflets minute; legumes very numerous, variously contorted; has been raised extensively at Hewra and Dapoorie from seed received through the late Dr. Wallich. This tree is likely to be of great importance on account of the excellent tanning material which it affords.

The seeds of the plant were introduced into Ceylon some years ago, and the result was that several of them germinated but died immediately afterwards, probably owing to the climate being too damp. On the other hand, this is what Dr. Trimen writes to the *Tropical Agriculturist* :

"Royal Botanical Garden, Peradeniya, 3rd Aug. 1881.

"SIR,—It may perhaps be instanced as a good example of the habit of passing by what is close to us without notice, that neither you nor your morning contemporary, in your remarks on 'Divi-Divi,' have seemingly been aware that the seeds of *Casalpinia coriaria* are regularly advertised in your columns, along with other useful plants on sale at these gardens. The fine old tree of this species near the entrance to Peradeniya affords an abundant crop of pods every year, and there can be no doubt that the plant would flourish generally at the lower elevations in Ceylon."

Dr. Cleghorn, in his "Forests and Garden of South India," says that small plantations of *C. coriaria* exist at Bangalore, Guntoor, Hunsoor, Masulipatam, &c., and that the tree grows well in most of these situations.

In November 1881, the Divi-Divi tree was thus alluded to in our columns :—

"A correspondent writes :—This plant, which grows in many of the outlying villages of Madras, and has been up to date uncared for, is now found to be a valuable article for tanning purposes. Large quantities of the pods these plants yield are being shipped to Europe, and in fact many persons have begun to pay some attention to the cultivation of this plant. A consignment of 88 bags of dried pods from this plant was shipped to England by the *Duke of Buckingham*." 173 trees of the Divi-Divi in full bearing, which would take an acre of land, is supposed to yield 50 cwt. of pods, which are valued in London at £37 10s.; and as the cultivation and care cost literally nothing after the trees are once in bearing, it is found to be a most profitable crop.

And a few months afterwards a correspondent of a local paper wrote as follows :—

"The Divi-Divi pods are employed for tanning purposes, as they contain 50 per cent of pure tannin. I have been told that in Bangalore there is a large plantation of this tree, and that its pods are largely used for giving the skins that superior smoothness remarkable in the Madras and Bangalore skins. I have also used Divi-Divi in dyeing, and I have employed a solution of acetate of iron after the bath in Divi-Divi tincture. The ink used in most of the Government Offices in Fort St. George is made with this plant. The cultivation of this elegant shrub is very easy. The seeds should be sown in March, and the young plants can be removed from the nursery during the following rainy season. They require some watering till they have attained the height of three feet, after which no more care is necessary. This plant grows luxuriantly in a clayish calcareous soil, but very slowly in red soil, as I have observed at the Red Hills near Madras. I think the difference in the growth in the two soils results from the clayish soil retaining moisture for a very long time in the summer, while in the latter the young plant is exhausted by the strong dry winds blowing then. But I think it still possible to cultivate this shrub in red soil with some success by adding dry mud from tanks to the soil before replanting the young tree from the nursery. Cow-dung ashes will prove useful round the plant. The great difficulty to contend with, however, in such soil is the want of water. The cultivation I have made for the last few years is quite a success, and I have made experiments in both soils; clayey as well as red. I shall feel obliged if any of your readers will give me some information regarding the market current price of this dye in London or elsewhere. I think that the high rate of freight from India to Europe will not allow a margin of profit in the shipment of Divi-Divi husks."

Toward the middle of last year the following appeared in a Calcutta paper :—

"The Superintendent of the Government Farm, Khandeish, recently shipped a consignment of Divi-Divi to the London market. Divi-Divi is the fruit of a tree which has some resemblance to the tamarind. It is used for tanning purposes, and meets with a ready sale. The consignment consisted of 14 cwt. and realized £10 7s. 1d., or close upon £15 the ton. From this sum, however, must be deducted the charge for freight, insurance, brokerage, &c., a deduction which brought down the balance to £8 17s. 7d.; which, at the rate of exchange at the time of the transaction, was equal to Rs. 83-1-1. The expenses of production in India had amounted to Rs. 29-7; accordingly the superintendent cleared a balance of Rs. 53-10-1. At these rates, for every ton of Divi-Divi sold in London the exporter might count upon a profit of Rs. 80. The advantages of the cultivation of the Divi-Divi tree are that it will grow in soil which is sandy and contains little nourishment, and is thus useless for average agricultural purposes, and that consequently, as may be imagined, the tree needs little attention and care. The demand in England can be reckoned upon as a fixed element."

In Chamber's *Encyclopædia* we find the following reference :—

"Divi-Divi or Libi-Dibi, the curved pods of *Casalpinia coriaria*, a tree which grows on the coasts of Curaçoa, Carthage, and other parts of tropical America. They have been long used there for tanning, but have recently acquired importance as an article of commerce. A considerable quantity is now annually brought to Britain. Divi-Divi is one of the most astringent substances known."

"A," writing from Nellore a few days ago, says :—

"Adverting to the enquiries of your correspondent PLANTER, I have the pleasure to intimate that Divi-Divi is the common name of the pod of the *Casalpinia coriaria*, a leguminous plant found in low marshy situations in the northern parts of South America. It is used both for dyeing and tanning, but chiefly for the latter purpose. The pod is from 2 to 3 inches in length by 3½ inch in breadth, and when in perfection, is of a rich brown colour. It contains a few small seeds, but the only valuable portion is the matter of a bright yellow colour, easily pulverised, which lies betwixt the outer skin and the husk that encloses the seed, and contains a large quantity of tannin. Divi-Divi is used not for the colouring principle but for its strong astringent quality as a mordant, and is used instead of sumach, which is scarce. In tanning it accelerates the process, and imparts to the leather a clean and healthy appearance. Mr. T. Ward at Madnapully is the owner of some trees there, and may probably be able to give more information, and also furnish seeds, if applied to."—*Madras Mail*.

THE LIME AND LIME-JUICE.

A CEYLON resident now in England, having noticed a query put by a correspondent in a recent issue regarding the lime and the profitability of its cultivation, has sent us a little pamphlet, entitled "The Island of Montserrat, West Indies, its History and Development, chiefly as regards its Lime Tree Plantations; with a short description of Lime-Fruit Juice and its use as a Medicinal Agent and a Beverage." The pamphlet opens with a description of the island, as follows :—

"The little Island of Montserrat, considered the most healthy of the Antilles, situated in 18° 45' north latitude, and 61° west longitude, and about eight miles in length from north to south, by a breadth of five miles from east to west, is composed of a small cluster of volcanic mountain tops, rising out of the Caribbean Sea to the height of 3,000 feet, the summits being more often concealed by floating clouds. These high mountains seem to protect Montserrat from the hurricanes which desolate the neighbouring islands as the forests ensure a rainfall when those islands are suffering from still more disastrous drought. The slopes from the hills to the sea are covered with emerald cane fields, or with the darker verdure of the lime orchards."

After a short summary of the history of the Island from its discovery in 1493 down to the present century, the writer says :—

"The first lime tree orchards were planted in 1852, by Mr. Burke, an enterprising planter then living in the island, but the speculation was at first by no means profitable, as this is an enterprise that involves a large outlay of capital, which is for a number of years unproductive, and even then only remunerative on a large scale; although the low rate of wages and extent of uncultivated land on a salubrious climate renders the Island of Montserrat particularly suitable for the purpose."

"The lime tree (*Citrus Limetta*) is a member of the orange tribe, which grows wild in many tropical countries, but does not flourish even so far north as the Azores. It is a thorny, bushy, evergreen tree, with handsome dark-green leaves. These are so fragrant that they are universally used in the West Indies to perfume the water in the finger-glasses at dessert. The small white flowers resemble orange blossom, and the scent is equally delicious."

"The plantations of the Montserrat Company already cover more than 600 acres, and contain 150,000 trees. These are generally planted fifteen feet apart, and the high road passes through them for a distance of more than two miles. No more beautiful sight can be seen than these orchards, when the trees are laden with their bright fruit, and at the same time the air is pervaded by the luscious fragrance of the blossom. The fruit is gathered by the negro women, and they carry it down in baskets on their heads."

"The important antiscorbutic properties of lime-juice have been well known for many years, and the refreshing lemonade which is made by mixing it with water and sugar is universally used in countries where the tree grows. The bulk of the lime-juice that is offered in the English market (and from which most lime-juice

cordials are manufactured) is made from the fruit of the trees that now grow wild so abundantly in Jamaica, Tahiti, and elsewhere. In some parts of Jamaica the negroes go about the country squeezing the fruit they find under the scattered trees into a pall with a wooden kitchen lemon-squeezer. This juice is bought by the merchants for a few pence a gallon. As lime-juice decomposes very rapidly when exposed to the atmosphere in a tropical climate, and acquires a disagreeable taste in a few hours, unless the air is excluded from it, it may easily be imagined that the juice so obtained does not please the English consumer, even if it had not, as is sometimes the case, been adulterated with salt water by the negroes to increase its bulk. In fact, until the introduction of the Montserrat juice, lime-juice was not popular as a beverage, on account of the mawkish taste which, as explained above, it so often carried with it.

"In order to ensure a regular supply of juice of reliable quality, extensive lime plantations were established more than twenty years ago, by Messrs. Sturge, of Birmingham, in the Island of Montserrat; where alone is the lime systematically cultivated on a large scale for the purpose of supplying juice as a beverage to the English market.

"This juice is brought over in large casks to this country, when, after being allowed to settle, it is clarified and bottled."

The writer also states that—

"Since the introduction of Montserrat lime-fruit juice, lime-juice or cordials prepared therefrom have undoubtedly become most popular beverages, and the fact that over 80,000 gallons are imported yearly from Montserrat shows the estimation they are now held in, and the important trade that has been developed."

CINCHONA.

ANALYSIS OF NILGIRI-GROWN CINCHONA BARK.

THE Madras Government some time ago forwarded to the Secretary of State consignments of cinchona bark, from their estates at Naddewatam, Dodabatta and Pykara, from which quinine and other alkaloids were to be manufactured on their behalf. These barks were made over to Mr. Whiffen, the well-known pharmaceutical chemist in London, and the analysis yielded the following results:—

| Description of bark. | Quinine sulphate per ct. | Cinchonidine sulphate p.ct. | Cinchona alkaloid p.ct. |
|-------------------------------|--------------------------|-----------------------------|-------------------------|
| Renewed crown bark... | 5.67 to 5.71 | 0.41 to 0.48 | 0.12 to 0.31 |
| Mossed "... | 4.06 to 4.3 | 1.4 to 4.5 | 0.2 to 0.24 |
| Natural "... | 3.6 to 3.42 | 1.02 to 1.21 | 0.15 to 0.23 |
| Renewed red bark... | 3.04 | 2.32 | 1.84 |
| Mossed bark... | 1.71 to 2.09 | 2.15 to 2.32 | 1.68 to 2.39 |
| Natural "... | 1.23 to 1.2 | 2.8 to 3.57 | 1.14 to 1.63 |
| Root "... | 1.3 to 2.09 | 2.1 to 2.15 | 2.39 to 2.57 |
| Branch "... | 0.8 to 0.68 | 1.5 to 1.35 | 0.47 to 0.51 |
| Renewed scraped crown bark... | 4.34 | 0.37 | 0.21 |
| Natural scraped bark... | 1.81 | 0.75 | 0.06 |
| Branch crown bark... | 0.7 | 0.16 | 0.04 |

The total of product obtained by manufacture was as follows:—

| | | |
|-----------------------|-----|------------|
| Quinine sulphate | ... | 1,467 lbs. |
| Cinchonidine sulphate | ... | 345 " |
| Quinidine " | ... | 40 " |
| Cinchonine alkaloid | ... | 208 " |
| Febrifuge | ... | 2,236 " |

Total charges on account of the bark sent amounted to £3,352-0-9, distributed as follows:—

| | | |
|--------------------------------------|----------|------------|
| Freight, agency, &c. ... | £. s. d. | 721 9 3 |
| Manufacturing charges ... | ... | 2,604 11 0 |
| Fire Insurance of bark at factory... | ... | 26 0 0 |

CINCHONA BARK.

MESSRS. ROBINSON and Dunlop have received for sale a number of small lots of Hakgalla Government bark—succirubra from trees 18 years old, officinalis 10 to 12 years old ledgeriana 3 years old, and callaya 5 years old. The results of analyses are very poor, and one may thereby be convinced that after 6 and 8 years the alkaloids do not increase with age. They are

Succirubra thick stem quill from 8 years old trees—sulph.

| | | |
|--|-----|------|
| quinine ... | ... | 2.41 |
| Do, stem and branch chips—sulph. quinine | ... | 1.72 |
| Officinalis, broken bold, quill from 10 to 12 years old trees—sulph. quinine | ... | 2.00 |
| Do, stems and branch chips—sulph. quinine | ... | 2.22 |
| Callaya stem and branch chips from 5 years old trees—sulph. quinine | ... | 1.35 |
| Ledgeriana stem and branch chips from 3 years old trees—sulph. quinine | ... | 2.63 |
| Total alkaloids | ... | 4.53 |

This is certainly a very curious result, but we think part of the explanation in the case of the succirubra bark is found in the unfavourable altitude and climate of Hakgalla (6,000 feet) for red bark, for trees 18 years old grown in the Wynad gave much better results. At the same time, Broughton established on the Nilgiris the decrease of quinine after the 6th year of succirubra trees, although the total alkaloids increased up to the 9th year when they also positively declined. Mr. Broughton's conclusion

was that the trees in question had passed the age of maximum yield, and he accounted for it by the growth of the bark at this age being mainly an increased development of liber fibres, and not cellular tissue. He also considers it as probable that a waste of the alkaloids commences from the first year, but is counterbalanced by the rapid simultaneous formation of alkaloid in the earlier years up to the 9th, when the formation becomes less active; and deterioration is the result.—The great value of ledger bark is strikingly shewn in the above table. We shall be glad if planters with experience of old trees will make the analytical results known.—Ceylon Observer.

FORESTRY.

IN the number of the *Forstliche Blätter*, of Leipzig, appeared an article entitled, "Relation between the frequency of thunderstorms and the mineral constitution of the soil," from which are taken the following observations, interesting to the student of Forest Science:—

"The Principality of Lippe-Deudold has an area of 20,000 square miles, and is divided into nine forest cantonnements.

"Mr. Feyer, Forest Inspector, made from 1874 to 1880 observations in regard to thunderbolts striking trees of the forest during that time, the results of which are embodied in the following table:—

| Year. | Number of thunderbolts. | Number of trees struck. |
|----------|-------------------------|-------------------------|
| 1874 ... | 14 ... | 14 |
| 1875 ... | 12 ... | 17 |
| 1876 ... | 23 ... | 37 |
| 1877 ... | 37 ... | 42 |
| 1878 ... | 21 ... | 21 |
| 1879 ... | 20 ... | 40 |
| 1880 ... | 56 ... | 67 |

During the last three years the observers gave attention to the different kinds of trees which were stricken. These were—oaks 77; beeches 14; other broad-leaved trees 4; resinous trees 44; oftener than once it happened that an oak and a beech have been struck at once by the same thunderbolt. From these data may be deduced with precision the danger to which each kind is exposed of being so struck if the number of trees belonging to each group were known. If we substitute for this the area occupied by each kind of tree we find:—

| Area. | Proportion per cent of area. | Proportion per cent of thunderbolt. |
|----------------------|------------------------------|-------------------------------------|
| Oak woodlands ... | 1880 | 10.5 |
| Beech woodlands ... | 11,840 | 70 |
| Other woodlands ... | 260 | 1.5 |
| Coniferous woods ... | 3,230 | 18 |
| | 100 | 100 |

From which it follows that the risk of being struck by a thunderbolt is, for the oak 60 by 10.5=5.7, while it is only 0.16 for the beech, 2 for other broad-leaved trees, and 1.5 for resinous trees. In other words, representing the risk for the beech as 1, it is 34 for the oak, 12 for other broad-leaved trees, and 9 for resinous trees.

"There is, then, a foundation of truth for the old saying that the beech is never struck by lightning; and if the ancient Germans honoured the oak as the dwelling-place of the God of Thunder, may it not have been that, living always in the open air, they may have remarked the preference of the lightning for this kind of tree?

"The observations made from 1874 to 1880, in the 18,000 hectares of extensive forest in the Principality have been grouped thus according to the nature of the ground, with the following results:—

| | Percentage of area. | Per cent of thunderbolt. | Risk for kind of land. |
|------------------------|---------------------|--------------------------|------------------------|
| Calcareous lands ... | 4,735 | 26 | 3 |
| Kuper marls ... | 5,640 | 31 | 10 |
| Argillaceous lands ... | 3,160 | 17.4 | 13 |
| Silicious land ... | 2,365 | 13 | 21 |
| Hard clay ... | 2,290 | 12.6 | 53 |
| | 100 | 100 | |

The numbers in the last column have been obtained by dividing those of the third column by those of the second; and they show in regard to different kinds of lands analogous to those which we have found to be the case in regard to different kinds of trees. For once that the lightning struck calcareous land it struck on a corresponding area four times marl land, seven times argillaceous land, 14.5 times silicious land, and 35 times the hard clay (*Lohm*). Countries, then, in which calcareous lands predominate are less exposed to damage by lightning than are those which consist of hard clay (*Lohm*); and the editor of the *Forstliche Blätter* remarks, that on calcareous land, the oak is in general much less abundant, while it is the species of tree predominating on the argillaceous *Lohm*, or mud land, and that it is in this fact we must look for the cause of the difference observed, rather than in the mineral composition of the soil. The deductions made would doubtless require to be confirmed by new observations, but they indicate at least in

what direction these researches must be prosecuted, and these commend themselves especially to observers in forest meteorological stations."

A COPAL FOREST.—The British Consul at Mozambique has recently reported the discovery of a considerable tract of copal forest. The forest is fully 300 miles long. It is a belt which runs parallel with the coast, and is midway between the coast and the first range of mountains. From Inhambane it is nearly 100 miles to get right into it. This distance is a little great, and may retard its being opened up, but its discovery adds to the known wealth of the district. "The native name of this gum," says the Consul, "is 'Stakate' and 'Staka.' The Zulu name for gum is 'Inthlaka.' The name 'Stacte,' mentioned in Exodus xxx, 34 (this is believed to be the gum of the Storax tree, *Styrax officinalis*), would be pronounced as the above-mentioned native name. The tree dominates over all, and, standing in any place overlooking the forest, you see here and there trees growing as it were in a hayfield. The gum has a beautiful odour if pounded and burned, also if boiled in a pot of water." The ordinary gum copal tree of the mainland of Zanzibar and Mozambique, though as a rule lofty, is by no means of the striking character here indicated.

THE TEACHING OF FORESTRY AT THE CENTRAL FOREST SCHOOL, DEHRA DOON.

FORESTRY being an art founded entirely on the observation of natural phenomena and the correct application of principles deduced therefrom, one of the most certain tests of a forester's aptitude for his profession is evidently the composition of a paper on some sylvicultural subject, to which he has devoted special attention. Accordingly, at the Central Forest School at Dehra Doon, it was decided to require the students, who were just completing their probation during the past season, to write an original essay on some subject selected by themselves, the essay to form an integral part of the final examination in forestry. This decision, for reasons which could not be helped, was only communicated to the students a fortnight before the examination; so that they had not the advantage, almost indispensable it must be admitted, of having previously followed out a connected series of observations all bearing on the one subject selected. Nevertheless, the essays are, I think, a fairly satisfactory proof of the progress made by the men, and as they will not only serve to give to the general public some idea of what we have been teaching at the Central Forest School, but at the same time also help to show to Indian foresters, the class of men we are preparing for the subordinate grades of our department, I send you selections from them for publication.

Critical readers will please to remember that these men form the first batch, who have gone through the entire course of instruction followed at the school; and that it is not from among the alumni of our Universities, men possessed of a high degree of general culture, that we can draw our recruits.

The men are all natives, and it would hence be superfluous for me to add that English is a foreign tongue for them.

The matter concerns us much more than the style and phraseology. I have, therefore, corrected the language of the extracts in so far as to make it intelligible English: the substance remains unchanged.

DEODAR IN KULU.

By MIAN MOTI SINGH.

FORESTS in which deodar is the prevailing tree are generally found on moist loamy soils. The deodar affects northerly and westerly aspects most, although it is not seldom met with on other aspects. Indeed, the aspect it selects varies, as a rule, with the altitude at which it grows. For instance, between 4,000 and 6,000 feet above the sea the tree grows gregariously on northerly and westerly slopes, and less commonly on easterly slopes, while *Pinus excelsa* very often forms pure forests on southerly aspects. Above 6,000 feet, on the other hand, it is on easterly and southerly aspects that deodar flourishes, growing there frequently almost pure, northerly and westerly slopes being occupied by the Himalayan spruce and silver fir.

The needles of conifer in the Himalayas form, when not burnt by fire, or triturated under the feet of cattle, a thick loose covering of undecayed vegetable matter over the soil. Deodar seeds that fall on such a covering, although they germinate freely enough, generally fail to extend their tap root through it into the soil below, the result being that they are either washed away with the dead leaves by the spring rains, or are killed by drought. On the other hand, young seedlings of *Pinus excelsa* develop a tap root capable of piercing this loose mass of undecomposed leaves, and forcing its way into the soil, where they thus fix themselves firmly.

The Himalayan spruce generally produces from two to three crops of seed during the interval between one seed year of deodar and another. And hence, when these two species grow together, this circumstance alone, irrespective of some others, gives the former species a decided advantage over the other.

The advantages of having oaks growing with deodar are many. I may mention some of the principal:—First, the deodar by itself, or associated with other conifers, cannot form a complete leaf canopy. When oaks enter the crop, these broad-leaved trees fill up all the intervals between the crowns of the cedars, without, however, diminishing the number of the latter. They thus force and hasten

the natural pruning of the cedar boles, and they increase the production of the soil. Secondly, none of our oaks attain anything like the height of deodar, so that the former constitute a true undercrop, making growth on their own account, and pushing up the latter. Thirdly, and lastly, the mixed crop so obviously forms a much more complete cover over the ground, the soil being thus continually protected and improved.

The people in the Himalayas prefer the leaves of oaks as fodder to those of any other trees, and even to the various grasses themselves. Oaks are also cut for fuel before any other species. Oaks are, therefore, very heavily lopped; and are hence kept down or destroyed, so that where they might grow usefully with the deodar, pines and small broad-leaved trees remain the only effective, but comparatively inefficient, allies of that valuable tree.

It is a well known fact that young deodar is greedily eaten by sheep and goats; and that, although the stem of young seedlings is remarkably elastic, the heavy buffalo tramples down and crushes thousands of them under his broad cloven foot. I would, therefore, exclude grazing from every area that is completely under our control. But when the undecayed layer of dead needles is so thick as to impede reproduction, I would admit cows in order to triturate the whole mass, facilitate its decomposition, and render it more compact.

Fire is not an annual occurrence in deodar forests, owing to the great altitude at which they often occur, and which preserves the moisture of the soil all the year round. But as the needles of conifers decompose very slowly, and are very resinous, they form a thick layer of highly combustible material, which, when once ignited, burns fiercely. Hence forest fires, when they do occur, are difficult to put out and do great damage. The only way to check or keep out fire is to trace fire lines, which should be kept clear of all combustible matter, and especially of cones. Unfortunately we have no deodar forests in the Punjab, which are thus protected. —*Indian Forester*.

THE GARDEN.

The Action of Manures on Fruits.—Cultivated plants are the inheritors of whatever benefits or disadvantages they may have derived from their predecessors. The thing is obvious enough to those who look on plants from an evolutionist's point of view; and the practical outcome is that, except under special circumstances, or for some special purpose, it is best, in our attempts to improve upon what we have got, to deal with a plant that has been in cultivation for a long time, and so avail ourselves of its stored-up inheritance. It would be a long uphill work to start afresh with the crab or wild pear, for instance, although for the sake of getting a new "break" or more robustness of constitution it may be desirable sometimes to begin again at the beginning, or at least to infuse some less conventionalised blood into our plants, if we may so speak. A curious illustration of the contrast between the wild and the civilised condition is afforded in Professor Goessman's paper on "Mineral Constituents in Plant Growth," in the *Transactions of the Massachusetts Horticultural Society*. The Professor has been experimenting on the difference in chemical composition between vines unmanured and vines manured. In the course of his experiments he analysed the juice of a wild vine (*Vitis labrusca*) grown without manure. And the juice of the same vine when treated with manure. At one bound the sugar rose from 8.22 per cent in the wildling without manure, to 13.67 per cent in the same wildling appropriately fed. This shows the advantage of the manure. But now, looking to the analysis of the cultivated variety (*Concord*), we find that in its juice, even when unmanured, the sugar amounted to 13.89 per cent, so that the cultivated variety, without manure at all, yielded a larger percentage of sugar than did the wild form with ample manure. The increase of sugar is coincident with a large increase of potash, and a largely diminished proportion of lime. In the case of strawberries the wild unmanured variety contains much less potash, much more lime, much less magnesia, much more iron, and about the same percentage of phosphoric acid as the cultivated and manured variety. The wild strawberry, moreover, contains one part of acid to two of sugar, while in the cultivated varieties the proportion of acid is one to four or more of sugar.

INDIAN PRIMULAS.—In the last number of the *Journal of the Linnean Society* is an interesting paper on some undescribed and little known Indian species of *Primula* and *Androsace* by Dr. George Watt, who has paid great attention to the order both in Sikkim and at the herbarium at Kew. The number of species of *Primula* enumerated is twenty-four, and of *Androsace* six, and the enumeration is accompanied by some notes by Sir J. D. Hooker. Several of these plants will doubtless soon be in the hands of our cultivators, on which account we think it well to call their attention to the publication of this paper with its numerous illustrations.

THE PLANTS OF MADAGASCAR.—At the last meeting of the Linnean Society a paper was communicated by Mr. J. G. Baker, containing descriptions of a large number of new species of *dicotyledons* of the *gamopetalous* series of natural orders, gathered in Madagascar by recent English collectors, especially the Rev. B. Baron, F.L.S., of the London Missionary Society. The most interesting of these novelties is *Schismatocladia*, a new genus of *Rubiaceae*, allied to *cinchona*. The other new genera are *Tetrastidum*, of the group of semi-parasitic *Scrophulariaceae*, such as *Pedicularis* and *Meclampyrum*, which turn completely black in drying, remarkable for its four shield-shaped one-celled anthers; *Forythopsis*, an erect shrubby *Acanthaceae* genus, with flowers like *Forythia*, and leaves not fully developed till after the flowers fade; and *Monachochlamys*, another genus of *Acanthaceae*, allied to *Mendoncia* and *Thunbergia*, with numerous small flowers, each contained in a persistent spathaceous bract like the hood of a Franciscan monk. Of repre-

representatives of well known European genera the present collection includes two species of *Anagallis* nearly allied to *Tenella*; two *Ajugas*, a *Salvia*, two *Micromeris*, three species of *Stachys*, five *Senecios*, three *Cynoglossums*, and a *Lysimachia*. The genera represented most largely are *Danais*, *Vernonia*, *Helichrysum*, *Gnertnera*, *Clerodendron*, and *Hypochoeris*. There is a single species of the beautiful *Acauthaceous* genus, — *Strobilanthes*, which is almost restricted to Tropical Asia. There is a new *Vicia* nearly allied to *Rosa*. Of endemic genera, known previously in the island, there are new species of *Aspilota*, *Epallage*, and *Oncostemum*. Of Cape types the principal are a *Ligilobotia*, a *Halleria*, an *Alectra*, and two heaths of the genus *Philippia*. — *The Gardener's Chronicle*.

NOTICE OF BOOK.

The Field and Garden Crops of the North-Western Provinces and Oudh, with Illustration by J. F. Duke, B.A., F.L.S., and Mr. J. B. Fuller, Assistant Director of Agriculture and Commerce, North-Western Provinces and Oudh, purports to be the first of a short series in which it is proposed to describe the cultivated products of these provinces, and to furnish, in a convenient form, all the information on the subject that is likely to be wanted by the student of Indian agriculture, or by the administrative officers of Government.

It was scarcely to be expected that all that might be said on the field and garden crops of the North-Western Provinces could be said in about one hundred pages, it is needless therefore to say that several of the topics are most inadequately treated, from an agricultural and commercial point of view, notably that of hemp. The botanical part of the work so far as it goes leaves little to be desired. The student of Indian agriculture and the administrative officers of Government could, we imagine, easily obtain access to the various *Gazettes* of the several Indian provinces where much valuable information, agricultural and commercial, is stored up. In the *Field and Garden Crops* references to authorities or sources of information are confined to the botanical part of the book, and no use has been made of volume X of the North-West Provinces Gazetteer; it has not even been referred to as a possible source of knowledge. The illustrations, while fairly well executed, on the whole are either defective or obscure in almost every plate, and the want of colouring detracts considerably from the popular usefulness and value of the drawings.

MINERALOGY.

FROM Perak the *Penang Gazette* learns that recent prospecting has proved that the alluvial deposits of Perak are very rich and extensive; the several districts in which tin oxide is being mined are being opened gradually, each producing the mineral in high percentage and of good quality, the development of which by primitive methods affords large profits to the mine owners, which may be increased by the application of improved appliances. A great number of square miles of rich tin land are available for tin mining: several of the different valleys have been opened and are being mined for their produce of tin ore which varies from 15 to 60 per cent. The deposits in the Kiuta district at Tapan are very rich; and also at Chauduriong, where enormous lumps of tin oxide are produced.

LIGNITE IN SOUTH ARCOOT.

SOME months ago, when boring for an artesian well in the village of Vargour (Bakour), eight miles south of Pondicherry, the auger, at 243 feet below the surface of the ground, came in contact with some lignite, the thickness of which was found to be 33 feet. The lignite was of a dark brown colour, passing into black, and showing at some places, small thin and bright particles; it was intermixed with iron pyrites of grayish colour, and we hear that the composition of it was as follow:—

| | | |
|-----------------------------|-----|------|
| Carbon .. | ... | 0.49 |
| Hydrogen oxygen and azot .. | ... | 0.40 |
| Asbes, &c. | ... | 0.11 |
| Total .. | ... | 1.00 |

and its calorific power about one-half of that of coals. The artesian well in which the lignite was found is situated two miles north of the Ponnear river, and three and a-half miles from the sea coast inland, in the alluvial basin of the Ponnear river, which is separated from that of the Gengée river by a rise, under ground, of the tertiary formation, the ridge having a direction from west to east parallel to two rivers.

These two basins each form a part of the large alluvium existing between Mercanum and Point Calymere, and which is superposed to the tertiary formation outcropping at the Red Hills near Pondicherry and at Mount Kepper, near Cuddalore, dipping again near Verdachellum to reappear near Tanjore. This tertiary formation has below the alluvium four principal depressions, which have been filled up by the disintegration of the tertiary formation itself and of the gneiss westwards, and have thus formed the alluvial basins of Gengée, of the Soucar, of the Vellar, and of the Cauvery rivers. The strata which have filled up the tertiary basins are generally composed of the same materials as proved by the thirty borings already made in a line parallel to the coast. They consist of the black clay deposited by the sea, of sands, pebbles, argillaceous mixtures and clays of different colour, from pyrites, and lignites sometimes in large quantities. In every boring which has been made lignite was found in a more or less advanced state of transformation and of variable thickness, the most remarkable deposit being that found at Vargour. From the above it may be surmised that if lignites are found in so many places and in such quantities, they can be found somewhere in those alluvial soils in important deposits. To return to the Vargour boring, a gentleman, (Mr. Deloncle), who was passing through Pondicherry at the time the lignite was tapped, and who had occasion to examine this product, obtained a lease for mining the deposit, and started a Company for the purpose. After having the specimens sent to Europe and analysed, the Company has despatched to India two mining engineers, with their staffs and boring apparatuses, for ascertaining the extent of the deposit, and the advisability or not of working out the Vargour lignite. These gentlemen are expected by the next French steamer.

If mining operations are undertaken, they will be executed without much difficulty, as it will be only necessary to pass the surface water sheet; from this to the bed of lignite below there is no other water-bearing stratum. Whether the 33 feet of lignite extends over a large area or not it is impossible at present to say, and as nothing is yet known of the future market price of this combustible, the future prospects of the enterprise cannot be ascertained until the report of the survey by the mining engineers has been published. If the combustible found at Vargour proves worth mining, this will encourage others to search for lignite beds, which may probably exist underground in the alluvium mentioned above.

SERICULTURE.

IT may not be generally known that in the valley of the Brahmaputra the respectable Hindoo is accustomed to walk in silk attire. This is no product of French or Chinese looms, but strictly of home growth and manufacture. Assam is happy in the possession of two indigenous varieties of silk worm, which prefer a simpler and more inexpensive diet than the traditional mulberry. One kind thrives upon a common forest tree; the other selects, out of the large range of vegetable life at its choice in Assam, the castor-oil plant as the food in which it luxuriates. The former species yields a silk with a beautiful yellow gloss, while the castor-oil worm spins a thread which can be woven into one of the most durable materials hitherto discovered. If neither sort of silk is of the very finest quality, both are admirably adapted for working into silk plushes and similar compound fabrics. When we add that the supply can be increased to almost any extent, it would appear that there is nothing more to say except that the silk industry in Assam is bidding fair to rival tea in importance. But the facts, unfortunately, are far otherwise. Both the production and the manufacture of silk have for years been steadily declining. The loom used to be an indispensable article of furniture in the old-fashioned Assamese household, and no girl had a chance of getting married unless she was able to weave garments for herself and her husband. But this laudable domestic custom is gradually dying out; Manchester piece-goods have almost hushed the household music of the loom by the banks of the Brahmaputra, as in the shires of England; and with the decay of the local market the breeding of silkworms has simultaneously decreased, while the price of silk has nearly doubled. The only hope for the trade now seems to be the creation of a market in France or England, and this must depend to a great extent upon the action of European capitalists, some of whom are already interested in the silks of India. At present the silk question in Assam—and indeed, it is believed in Bengal generally—presents this extraordinary aspect, that though the cost of feeding the silk worms is really insignificant, and the facilities for the extension of sericulture are practically limitless, yet the cocoons of one of the best species cannot be got in the

market at all, while those of another cannot be got at the price which European manufacturers are prepared to pay. This is a state of affairs which cannot be altered without patience and capital, but anybody leashed in silk, and sufficiently qualified in these two respects, ought to make a good thing out of the Assam silk business after a few years.

SERICULTURE IN CEYLON.

A CORRESPONDENT sends us two very nice-looking cocoons, to show what is being done in Galle, and he writes:—
We are indeed very glad in being able to say that Father Palla has experienced considerable success in the culture of silkworms in this country. The successful results which have attended his efforts in this industry for the last three years convince us, despite the adverse views of some as to its success, that the culture of the silkworm can be carried out, beyond a doubt, to such a great advantage in this country, as to be made a very remunerative and profitable industry, if conducted with due attention and care. Father Palla's object in attempting this enterprise was, as we see, for no other reason than that of proving to the colony that silk production can be carried to undoubted success in this country; and his successful experience for upwards of three years in this enterprise, we dare say, warrants him in saying that he has realized the object he aimed at. Although it was said by some, whose experience in this industry falls short of the mark, that the mulberry plant, the chief aliment of the silkworm, does not grow freely in Ceylon, yet we have no hesitation in saying that Father Palla's successful experience in the cultivation of the plant, places us beyond the shadow of a doubt that the mulberry plant grows very freely in any place in Ceylon. Mr. Geddes also concurs in this opinion, but it must be conceded that it does not thrive so luxuriantly as it otherwise would in somewhat cooler climates than Ceylon; but however this may be, it thrives so luxuriantly in Ceylon, as to ensure success in the culture of the silkworm, and Father Palla's mulberry plantation in Galle is a proof of this. It was also said that the silkworm eggs of the second production become spoilt and useless, and that a fresh supply of eggs is required to be imported from Japan or elsewhere. But we have seen the eggs of the fifth production, and from our own personal observation, we can say that they appear to be of superior quality to those of the primary production, and moreover we learn from letters received by Father Palla from Germany, Italy, England, &c., that the cocoons sent by him from Ceylon were so much appreciated and admired, as to render it desirable for them to apply to him for eggs.

First, it is essentially necessary, before the rearing of silkworms in sufficient quantity for commercial purposes can be successfully attempted, to have a good plantation of mulberry. This is of paramount importance to ensure success in the enterprise.

Secondly, an apartment or room as in India is much needed to keep the worms safe from being exposed to the danger of easily falling victims to lizards, scorpions, ants, and such other plagues. This, we say, as it has been said to us from Father Palla, who has experienced such destruction.

Thirdly, it must be also one of the main considerations with the sericulturist to secure the services of an expert in the rearing of the silkworm, i. e., one who has especial knowledge in the culture of the worm—"education" as it is called of the worm; for practical knowledge is more needed than theory for carrying on the business successfully. It is therefore no wonder that those who have overlooked these precautions have met with ill-success in the enterprise.

We are glad to hear that several persons, following in the wake of Father Palla, are devoting much time and care to this pursuit. We wish them every success in their endeavours, as with a little experience it can be made a very profitable industry for the natives of this country. It will also give great pleasure and satisfaction to Father Palla, to hear of their success, and to know that his endeavours to give the natives of this country the benefits of an industry so long overlooked have not been fruitless.

There can be no doubt that the mulberry flourishes in Ceylon, and Father Palla's experiments prove that the silkworm can be propagated here to the fifth generation. The commercial question then hinges on an abundance of cheap labour. In the great silk-producing countries, Italy, Japan, China, &c., much of the work is done by the women and children of families. It would be a great step in advance if women and children in native families here would devote themselves to the pursuit.—*Ceylon Observer*.

TEA.

THE following is a description of Mr. C. Shand's Patent Tea dryer:—

The barbecue-shaped steam-heated tea-dryer is the cheapest, most economical, and safest drying machine. As this machine can be made any length and width, the quantity of leaf which can be manufactured is only limited by the extent of drying surface. One, five feet wide, and fifteen feet long, will admit of about forty pounds of tea being spread as thinly as on sirocco trays, and, if heated to one hundred and fifty degrees Fahrenheit, would dry a maund per hour. The steam for heating this galvanized iron drying surface is generated in the space (3 inches) between it and the thin boiler plate bottom. The machine, which is made steam-tight, is partially filled with water, and placed on a fire stove. It is evident that a comparatively small quantity of fuel will

generate sufficient steam to heat a large surface, especially if the smoke flue is placed under the whole length of the machine. As it is impossible to fire-burn the tea, dried by the steam-heated dryer, the enormous advantage of being independent of the care and judgment of coolies, and of the necessity of uninterrupted European supervision, is too evident to require comment.

Mr. Shand says:—It is not intended to sustain any pressure of steam, the drying surface cannot easily be heated over 150 degrees (°)

As a matter of course, the tea takes a longer time to dry than when made by siroccos, in which the temperature is maintained at 275 degrees, but the extent of drying surface available makes this a matter of secondary importance.

Mr. Shand does not mean that no care or attention is required to keep up fire and supply boiling water periodically from a cistern placed over the flue; but it can be understood that the same care, judgment, and observation is not required to dry tea at a comparatively low temperature as at a very high one; for instance, it does not injure coffee to allow it to remain on the barbecue after it is thoroughly dry; but put it in a roaster, and what care and judgment is not required to perfect the roasting! No doubt, by the use of siroccos and other modern appliance, the risk of fire-burning is now greatly diminished, but these still require great care in shifting the trays and watching the thermometer. This constant watching is obviated by the use of Mr. Shand's machine, and all the superintendent has to do is to feel when the tea becomes crisp and dry; he has the security that, if this is neglected to be done at the moment it is sufficiently dry, no injury takes place by its remaining on the heated surface.

The machine is especially adapted for redrying tea before packing, this being an operation carried on at a low temperature, and requiring a good deal of care.

There are, it is well known, two difficulties connected with the proper manufacture of tea, requiring at present the constant supervision of the superintendent: these are fermentation and firing. If the necessity of closely watching the latter can be dispensed with, it gives the superintendents more time to direct the fermentation, on which the colour of the infused leaf, and consequently the value so greatly depends.

TEA AND CLIMATE IN INDIA AND CEYLON.

THE *Indian Tea Gazette* in noticing the discussion on the probable rate of bearing per acre of tea in Ceylon, very naturally denounces "Cha's" estimates of 700lb. for low estates and 400lb. for high, as exaggerated. Time will show; but no time is needed to elapse in order to shew the incorrectness of the premises on which the Indian editor argues. He states: "perhaps Darjeeling and the Doonars would best represent the high and low elevations, respectively, at which tea can be successfully cultivated in Ceylon; and the climatic conditions of the places named are almost identical." The meaning of the passage we have italicised is, of course, that the climate of the Doonars is identical with that of the low country of Ceylon in which tea is cultivated, and that the climate of Darjeeling is the counterpart of that of our hill country. To shew how baseless this statement is, we need merely mention, that at this moment and always in the season between November and March, the heavily pruned tea of the Eastern Himalayas, is enjoying the rest of a very pronounced winter, while it is in those very months that tea in Ceylon yields its most luxuriant flushes. The difference of climate is all that is implied in the facts that while Darjeeling and the Doonars are in the interior of a vast continent and on or at the foot of the most gigantic mountain system in the world (its very name signifying "The Abode of Snow,") and 27° north of the equator: Ceylon is an island, twenty degrees nearer the equator than Darjeeling and the Doonars and in the track of both monsoons. The climatic conditions, therefore, so far from being identical are about as opposite as well can be. Warmth and moisture are the prevalent characteristics of our Ceylon climate. Frost is so rare a phenomenon, even on the most elevated forest-land on which tea is cultivated in Ceylon—Oliphant estate, above Nuwara Eliya, to wit—as to be not worth taking into account, while devastating hailstorms, such as frequently play havoc with tea in Northern India and Assam, are utterly unknown in Ceylon. Such cold as we experience at this season of the year is powerless to check the growth of tea, and our winter, as far as tea is concerned, is in the heavy rains and strong winds of the south-west monsoon months, June—August, when the bushes are pruned. While in most of the tea districts of India the vast bulk of their rainfall occurs in from four to six months, ours is fairly distributed over the year. Indeed the objection offered in the experimental era of the tea enterprise in Ceylon was our chronically wet climate, and there can be no doubt that in a good many places, on the hills, the process of "withering" is rendered difficult by the prevalence of rain and mist. This is a difficulty not unknown in Darjeeling in the months, June—September. Had the editor of the *Tea Gazette* claimed for Darjeeling and especially for the Doonars, a more fertile soil than Ceylon can generally shew, we could better understand the argument. But we have good tea soil in a healthy climate. Into the Terra! at the foot of the Darjeeling hills the debris of the Himalayas have been pouring, perhaps for thousands of centuries, so that the rich black soil is, in places, forty feet deep. The Doonars have much the same conditions of soil and, unhappily of climate. All places at the base of mountains in India are insanitary, and even up to 3,000 feet, fever is the frequent result of

a climate made up of half the year very heavy rain and for the next half practically none. We are now at the commencement of our dry season in Ceylon, and our hill climate is simply delicious, being kept healthy by genial showers of rain at intervals rarely or never one month apart. In soil alone, therefore, if even in tea soil, is Ceylon inferior to India. Experienced Indian tea planters, like "Cha," have after sufficient comparison, given the palm of superiority to Ceylon, and Mr. Sandison, after having cultivated tea and contracted fever in Assam, and visited Darjeeling and all the other great tea districts of India, states decidedly that he saw nothing better than what exists in Ceylon for successful tea production.—*Ceylon Observer*.

TOBACCO.

TOBACCO CULTIVATION IN THE WEST INDIES.

FOR some years past the superior quality of the tobacco grown in Jamaica has been steadily forcing itself on public recognition, and Jamaica cigars seem likely to take rank alongside those produced in Cuba, which, taking their name from the capital of that island, have come to be recognised as the type of excellence in this particular form of the "fragrant weed." The cultivation of tobacco was an industry of some importance in the Lesser as well as the Greater Antilles, but it has died out in the former, though that is no apparent reason why the cultivation of the plant should not be revived there. The plant has been introduced from Cuba into the Bahamas, where it promised excellent results—although it would appear that, probably owing to the expense of initiating the industry, the Government has not continued the

experiments—and Governor Robinson, struck with the similarity between the climate, soil, and rainfall of Cuba and those of St. Lucia, has induced the Legislative Council of the latter island to vote a sum of money with the object of introducing the "new product" into the colony. A "Tobacco Committee" has been appointed to enquire into the subject, and the result of their investigation is embodied in a report which has just been issued. Some seed of the "best Havana tobacco"—procured, it is to be noted, from the Botanical Gardens of Jamaica—was entrusted to four gentlemen, who undertook to give it a fair trial; and although it is too early yet to judge of the eventual results of the experiment, the seed is reported to have germinated and to be progressing favourably, and there seems every reason to anticipate a successful result. There is in St. Lucia an abundance of soil of a suitable nature, with ample shade and rain, and many different "aspects," while the whole climate and physical features of the island approximate very closely to those of Cuba. The principal difficulty, indeed, in the way, seems to lie in the proper curing of the leaf. Sir Joseph Hooker endorses Governor Robinson's statement, that the finest tobacco in the world may be spoiled by improper or inefficient curing; and he quotes an instance in which ten bales of Ceylon tobacco, sent recently to the London market as an experiment, fetched a low price in consequence of the centres having been decomposed during the voyage, through some defect of curing or packing. With the care with which Governor Robinson and the authorities of St. Lucia have gone into the matter, there is little fear of such a mistake being made there, and their experiment will be watched with interest in the colonies. Tobacco requires a soil rich in potash, and while calcareous and clayey soils are to be avoided, alluvial lands on the banks of streams, not too wet, are most favourable. Plenty of manure is required, as the plant rapidly exhausts the soil; but chlorides must be scrupulously avoided. Slow desiccation, without exposure to sun or wind, and sound fermentation, are the two main points to be observed in the preparation of the leaf for the market.

ZULULAND AND CETEWAYO.

"I know what it is," he answered; "this honey is made from euphorbia flowers, which are very poisonous." This explanation made me feel exceedingly uncomfortable; but I elicited from him that there was not much danger, as the 'masses' taken with it would neutralise the effect of the poison. Directly he mentioned poison I dived into the packs, and pulled out a bottle of ENO'S FRUIT SALT, and emptying a quantity into two panuikins, filled them up with water, and several times repeating the dose, in a few hours we were considerably better."—*Zululand and Cetewayo*, (p. 139), by Captain W. R. Ludlow, 1st Batt. R. V. Royal Warwickshire Regiment.

"What on earth shall I take to Zululand?" asked my friend Jim Law one day at Aldershot, when he had just received orders for South Africa, to start at forty-eight hours' notice. I replied, 'If you take my advice—and it's that of an old traveller—you'll not budge without a few bottles of ENO, even if you leave half your kit behind. I never am without these Salts, and, please the pigs, never intend to be.' On his return I inquired, 'Well, how about ENO'S FRUIT SALT?' 'My dear fellow, it was the best advice you ever gave; they saved me many an illness; and when I left Tugela, I sold the remaining bottles for ten times the original price!'—*Lieut.-Col.*

JEOPARDY OF LIFE. THE GREAT DANGER OF DELAY.

You can change the trickling stream, but not the raging torrent.

WHAT EVERYBODY SHOULD READ.—How important it is to every individual to have at hand some simple, effective, and palatable remedy, such as ENO'S FRUIT SALT, to check disease at the outset! For this is the time. With very little trouble you can change the course of the trickling mountain stream, but not the rolling river. It will defy all your tiny efforts. I feel I cannot sufficiently impress this important information upon all Householders, or Ship Captains, or Europeans generally, who are visiting or residing in any hot or foreign climate. Whenever a change is contemplated, likely to disturb the condition of health, let ENO'S FRUIT SALT be your companion; for, under any circumstances, its use is beneficial and never can do harm. When you feel out of sorts, yet unable to say why, frequently without any warning you are suddenly seized with lassitude, disinclination for bodily or mental exertion, loss of appetite, sickness, pain in the forehead, dull aching of back and limbs, coldness of the surface, and often shivering, &c. &c.; then your whole body is out of order, the spirit of danger has been kindled, but you do not know where it may end: it is a real necessity to have a simple remedy at hand that will answer the very best end, with a positive assurance of doing good in every case and in no case any harm. The pilot can so steer and direct as to bring the ship into safety, but he cannot quell the raging storm. The common idea when not feeling well is, "I will wait and see, perhaps I shall be better to-morrow;" whereas, had a supply of ENO'S FRUIT SALT been at hand, and use made of it at the onset, all calamitous results might have been avoided. What dashes to the earth so many hopes, breaks so many sweet alliances, blasts so many auspicious enterprises, as untimely death?

ENO'S FRUIT SALT.—"After suffering for nearly two and a half years from severe headache and disordered stomach, and after trying almost everything and spending much money without finding any benefit, I was recommended by a friend to try ENO'S FRUIT SALT, and before I had finished one bottle I found it doing me a great deal of good, and now I am restored to my usual health; and others I know that have tried it have not enjoyed such good health for years—Yours most truly, ROBT. HUMPHREYS, Post Office, Barrasford."

SUCCESS IN LIFE.—"A new invention is brought before the public, and commands success. A score of abominable imitations are immediately introduced by the unscrupulous who, in copying the original closely enough to deceive the public, and yet not so exactly as to infringe upon legal rights, exercise an ingenuity that, employed in an original channel, could not fail to secure reputation and profit."—*ADAMS*.

CAUTION.—Legal rights are protected in every civilized country. Examine each Bottle, and see the capsule is marked "ENO'S FRUIT SALT." Without it you have been imposed on by worthless imitations. Sold by all Chemists, price 2s. 6d. and 4s. 6d.

DIRECTIONS IN SIXTEEN LANGUAGES HOW TO PREVENT DISEASE.

Prepared only at ENO'S FRUIT SALT WORKS HATCHAM, LONDON, S.E., by J. C. ENO'S Patent.

THE ART OF CONQUEST IS LOST WITHOUT THE ART OF EATING.—DINNER ENGAGEMENTS.—STIMULANTS.—TOO RICH FOOD.—LATHOURS.—INSUFFICIENT EXERCISE.—EXCITEMENT, &c.—A gentleman writes: "When I feel out of sorts I take a dose of ENO'S FRUIT SALT one hour before dinner or first thing in the morning. The effect is all I could wish." How to enjoy good food that would otherwise cause biliousness, headache, or disordered stomach—use ENO'S FRUIT SALT.

THE GREAT REMEDY FOR PRICKLY HEAT, INDIGESTION, HEADACHE, BILIOUSNESS, AND FEVERS.

LAMPLOUGH'S PYRETIC SALINE,

As possessing elements most essential for the restoration and maintenance of health with perfect vigour of body and mind.
It is Effervescent and Tasteless, forming a most Invigorating, Vitalizing, and Refreshing Beverage.
Gives instant relief to HEADACHE, SEA or BILIOUS SICKNESS, CONSTIPATION, INDIGESTION, LASSITUDE, BRUISES, and FEVERISH COLIC; prevents and quickly cures the worst forms of FEVER, BOILER, JUNGLE, and other FEVERS, SMALLPOX, MEASLES, and ERUPTIVE or SKIN COMPLAINTS, and various other altered conditions of the blood.
Dr. FLOUKE—"Preventing access of impurities harmful to mankind."
Dr. MORRIS—"It purifies the blood with its just saline constituents."
GOVERNMENT OFFICIALS AND PLANTERS caring for the welfare of their employes should note its value as a specific in Fever cases.
Dr. J. W. DOWLING—"I used it in the treatment of forty-two cases of Yellow Fever, and am happy to state I never lost a single case."
Dr. W. F. FRYER—"Since its introduction the Fatal West India Fevers are deprived of their terrors."
HIS EXCELLENCY THE GOVERNOR OF SIERRA LEONE, in a letter of request for an additional supply of the Pyretic Saline, states—"It is of great value, and I shall rejoice to hear it is in the houses of all Europeans visiting the tropics."
To be obtained of any Chemist or Drug Store, in Patent Glass-stoppered Bottles, 2s. 6d., 4s. 6d., 11s., and 21s. each.
Please note in connection with the recently observed effects of the use of Citrate and other preparations of Magnesia that LAMPLOUGH'S PYRETIC SALINE is warranted not to contain any substance which would cause calculous or other earthy deposits.

H. LAMPLOUGH, 113, HOLBORN HILL, LONDON, E.C.

GOVERNMENT

CINCHONA FEBRIFUGE.

An efficient substitute for Quinine. Sold by the principal European and Native Druggists of Calcutta. Obtainable from the Superintendent, Botanical Gardens, Calcutta. Post free, at 4 oz., Rs. 6; 8 oz., Rs. 11; 16 oz., Rs. 20-12. Cash with order.

1

PLANTERS' STORES & AGENCY CO., LIMITED,

MERCHANTS AND GENERAL AGENTS,

Calcutta,—30, STRAND.

General Manager—W. E. S. JEFFERSON.

Manager—

Agencies for Tea Estates undertaken on the most advantageous terms.

Coolies recruited by our own staff of experienced Agents, with Depôts throughout Chota Nagpur and at Dhubri.

Indentors and Consignees of all merchandize.

Army, Navy, Civil Service, and Private Agents.

Assam.—"THE EXCHANGE," DIBRUGARH.

W. J. WHEATLEY, Manager.

A. D. STUART, Agency Superintendent.

Direct Importers of every requisite for Tea Estates and European Residents.

Price Lists on application.

Agents for India General Steam Navigation Co., Ltd.; Agents for Commercial Union Assurance Co., Fire and Life;

Agents for "Star" Line Ocean Steamers,

Calcutta to London; Agents for

Reuter's Telegram Co.,

Limited.

London.—GREAT WINCHESTER-STREET, E.C.

E. G. ROSE, Secretary.

Agencies at Birmingham, Bordeaux, and Charente.

FRANCE.

CONTINENTAL & COLONIAL AGENCY

(LICENSED),

14, RUE DE CHABROL, PARIS.

Transacts every description of Commission, Merchant, and General Agency Business.

All Indents executed at Manufacturers' most favourable terms.

Conditions.—Two and-a-half per cent. Commission when Banker's Draft on London or Paris accompanies order. Special terms to regular correspondents. All Discounts conceded to purchasers, Original Invoices sent when required.

Produce taken charge of and realised to best advantage. Cash advanced on Consignments.

The Agency Represents, Buys, and Sells for Firms.

Public Securities, Estates and Properties, bought and sold. Loans, Mortgages, Mines, and Industrial Investments, &c., negotiated. Manufacturers and Producers can have suitable articles introduced to the markets on advantageous conditions.

PRICE LIST—comprehensive and reliable—on application.

BANKERS.—PARIS: George Waters, Esq., 30, Boulevard des Italiens. LONDON: The London and County Bank 3, Victoria-street, Westminster.

Address: The Manager, Continental and Colonial Agency, 14, Rue de Chabrol, Paris, France. 447

NOTICE

TO MANUFACTURERS,

AND

OTHER USERS OF POWER IN BULK.

WATER POWER, varying from 100 to 1,000 H.P., is available at 38 sites on the Bari Doab and Western Jumna Canals in the Punjab.

The tracts in which the Water Power is situated are—

(a) Between the rivers Beas and Ravi, to the north of the Scinde, Punjab and Delhi Railway, 26 sites, close to the Umritsur and Pathankote Railway now under construction.

(b) To the west of, and about 16 miles from the river Jumna, 12 sites, on a navigable canal running from Kurnal to Delhi, and within easy distance of the Grand Trunk Road.

Lease will be granted for 20 years, on the following approximate rates per H.P. per annum:—

| | | | | |
|-----------------------|-----|-----|-----|----------|
| For the first 3 years | ... | ... | ... | Rs. Nil. |
| " " second 5 " | ... | ... | ... | " 60 |
| " " third 6 " | ... | ... | ... | " 100 |
| " " fourth 6 " | ... | ... | ... | " 150 |

Full particulars can be obtained from the Office of the Joint-Secretary to Government, Punjab, Irrigation Branch, Lahore, and information, regarding the Water Power available at the various sites and their local advantages, can be obtained from the offices of the Superintending Engineer, Bari Doab Canal, Umritsur, and Superintending Engineer, Western Jumna Canal, Delhi.

By order,

R. HOME, Lt.-COL., R.E.,

Offg. Joint Secy., Govt., Punjab,

PHOENIX IRON WORKS, CALCUTTA. THE OLDEST ENGINEERING ESTABLISHMENT IN INDIA, JESSOP & CO.,

**Civil and Mechanical Engineers, Contractors, Brass and Iron Founders,
Metal Merchants, &c.**

*Forged and Cast Iron Work, Boilers, Machinery for Jute, Cotton and Rice Mills, Collieries, Indigo Concerns, Tea Gardens, &c.,
Contractors' and Brick-making Plant, and every class of Iron and Brass Work made to order.*

SOLE AGENTS FOR

Robey & Co's celebrated Portable and Fixed Engines and Machinery, Gwynne & Co's "Invincible" Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

IMPORTERS AND MANUFACTURERS OF EVERY DESCRIPTION OF STEAM ENGINES AND MACHINERY.

Robey & Co's Portable, Horizontal, Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand, Lift and Force Pumps, Tangye's "Special" Steam Pumps, "Vauxhall" Donkey Pumps, Flour Mills, Soorkee Mills, Pug Mills, Brick-making Machines, Road Rollers, Saw Benches, Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines, Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selkirk's Boiler Tube Benders, Steam Pressure Recorders, Electric Pens, Richard's Engine Indicator, Gifford's Injectors, Cooking Stoves, Fire-Proof Safes.

The following are the principal advantages of the "Invincible" Pump:—

1st.—It is arranged to swivel on the bed plate, and may be placed at any angle simply by slackening a few nuts, without interfering in any way with the bed plate or the joints of either the suction or discharge pipes.

2nd.—It does not require a foot valve, being fitted with small air exhauster and clack on discharge which always keep the pump charged ready for work.

3rd.—The bearings are made on an entirely new principle, and one bearing will last out four of the old arrangements.

**J. & H. GWYNNE'S
"Invincible" Centrifugal Pump.**

4th.—The form of the pump casing is so arranged that one side can be taken off in a few minutes for the inspection of the whole of the disc and interior of the pump.

5th.—Hand holes are made on each side of the suction pipes to enable any foreign matter which may get into the pump or disc to be easily removed. The covers are fitted with a bayonet joint so that they can be removed and replaced in less than a minute.

6th.—The "Invincible" is 25 per cent. lighter than any other Centrifugal Pump in the market, and discharges at least 10 per cent. more water for the power applied.

Ransome's Indian Plough. Price, Rs. 15.

Howard's Ryots' Plough. Price, Rs. 20.

These Ploughs have been expressly designed and manufactured for the use of the Ryots of India, whose special needs have been carefully studied in their construction. They embody all the qualifications for which the native-made implements have hitherto been preferred, whilst being incomparably superior in strength, durability, and efficiency.

MORAE'S PATENT SUB-SOIL AND GENERAL PLOUGH

Stirs up the soil to three times the depth of a native plough, and leaves the good mould on the top. Goes through the dirtiest land without getting choked with weeds. Price, Rs. 15.

INDIGO AND TEA PLANTERS' IMPLEMENTS AND STORES.

ENGINEERS' TOOLS AND STORES OF ALL KINDS.

ALWAYS ON HAND A LARGE STOCK OF PLATE, BAR, ANGLE, TEE AND CORRUGATED IRON, STEEL, BRASS, COPPER, PIG IRON, FOUNDRY COKE, SMITHY COAL, FIRE BRICKS, AND FIRE CLAY.

Catalogues on Application.

GOODALL'S Household Specialities.

A Single Trial solicited from those who have not yet tried these Splendid Preparations.

YORKSHIRE RELISH.

The Most Delicious Sauce in the World.

This cheap and excellent Sauce makes the plainest viands palatable, and the daintiest dishes more delicious. With Chops, Steaks, Fish, &c., it is incomparable. In bottles, 6d., 1s., and 2s. each.

GOODALL'S BAKING POWDER.

The Best in the World.

Makes delicious pudding without eggs, pastry without butter, and beautiful light bread without yeast. In 1lb. packets, 6d., 1s., 2s., and 5s. tins.

GOODALL'S QUININE WINE.

The Best and most Agreeable Tonic yet introduced.

The best remedy known for Indigestion, Loss of Appetite, General Debility, &c. Restores delicate individuals to health. At 1s. 1½d. and 2s. 3d. each bottle.

GOODALL'S CUSTARD POWDER.

For making Delicious Custards without Eggs, in less time and at half the price.

The Proprietors can recommend it to Housekeepers generally as a useful agent in the preparation of a good custard. GIVE IT A TRIAL. Sold in boxes, 6d. and 1s. each.

GOODALL'S GINGER BEER POWDER

Makes Three Gallons of the Best Ginger Beer in the World for Threepence.

The most valuable preparation for the production of a delicious and invigorating beverage. It is easily made, and is by far the cheapest and best Ginger Beer ever offered to the public. Sold in packets, 3d. and 6d. each.

GOODALL'S EGG POWDER.

Its action in Cakes, Puddings, &c., &c., resembles that of the egg in every particular. One penny packet will go as far as four eggs! and one sixpenny tin as far as twenty-eight. Sold everywhere, in 1d. packets; 6d. and 1s. tins.

GOODALL'S BLANCMANGE POWDER

Makes delicious Blancmange in a few minutes. In boxes at 6d. and 1s. each.

All the above-named Preparations may be had of all Grocers, Chemists, Patent Medicine Dealers, and Oilmen.

Proprietors: GOODALL, BACKHOUSE & CO, Leeds, England.

FREEMAN'S SYRUP OF PHOSPHORUS.

Nature's Great Brain and Nerve Tonic and the most wonderful Blood Purifier. The highest Medical Authorities say that it is the only Cure for Wasting Diseases, Mental Depression, Loss of Energy, and Stomach Complaints.

It is pleasant to the taste, and might be taken by the most delicately constituted. In the most enfeebled it builds up a NEW AND HEALTHY CONSTITUTION. One dose of this Remedy is equal to Twenty Doses of Cod-Liver Oil.

Thousands have been snatched from the brink of the grave by the timely use of FREEMAN'S SYRUP OF PHOSPHORUS. May be had of all Chemists and Patent Medicine Vendors, in bottles at 2s. 9d., 4s. 6d., 11s., and 38s.

MESSRS. SUTTONS' SPECIAL EXPORT BOXES OF SEEDS.
BEWARE OF IMITATIONS.

NOTICE.

SUTTON'S SEEDS & CATALOGUES

MAY BE HAD OF DULY AUTHORISED AGENTS

IN EVERY PART of the WORLD,

INCLUDING—

The Proprietors, *Indian Agriculturist*, Chowringhee-road, Calcutta; the Great Eastern Hotel, Company, Limited, Calcutta; Messrs. Wilson, Mackenzie & Co., 13, Old Court House-street, and 1, Mangoe-lane, Calcutta. Orders received by Messrs. King, Hamilton & Co., Calcutta.

NOTICE.

In ordering through London Shippers, purchasers should be particular to stipulate for SUTTON'S SEEDS.

TESTIMONIAL.

From S. Jennings, Esq., late Vice-President of the Agri-Horti Society of India.

"With reference to your mode of packing seeds for export, I must say how much I was gratified with the system you were so good as to show me. During the whole of my long Indian experience, it was my constant regret that English packet seeds were almost invariably lower in germinating power than the American. After seeing the elaborate precautions you take in executing such orders as that of the Agri-Horti Society of India, I am by no means surprised to hear that you have been gratified by the receipt of so much testimony from the tropics as to the condition of your Seeds upon arrival."

S. OWENS & CO.,

WHITEFRIAR'S-STREET, LONDON.
HYDRAULIC ENGINEERS AND MANUFACTURERS OF
PUMPING MACHINERY OF EVERY DESCRIPTION
FOR STEAM, WATER, WIND, CATTLE, AND MANUAL POWER.

Hydraulic and Screw Presses, Oil Mill Machinery, Hydraulic Lifts, &c.

SOLE MAKERS FOR GREAT BRITAIN OF

BLAKE'S PATENT DIRECT-ACTING STEAM-PUMP,—MORE THAN 10,000 IN USE.

THE FOLLOWING ARE SOME OF THE PROMINENT ADVANTAGES OF THE BLAKE PUMP:—

It will start at any point of stroke.
It has no dead point.
It works fast or slow with the same certainty of action.
It is economical. Has a lead on the Slide Valve.
It is compact and durable.

BLAKE'S PATENT
Direct-Acting Steam Pump and Boiler Feeder.

Oil Mills, for Steam or Cattle Power.

It is interchangeable in all its working parts.
It will deliver more water than any other Pump.
It is made of best materials in the most workman-like manner.
Can be worked at 200 strokes per hour, or 20 strokes per minute.

Double-barrel Contractors' Pumps, for Hand or Steam Power.

Double-barrel Fire Engine, for Manure, Factories, &c.

Deep-well Pump for Hand Power.

Fire Engine, for Towns, Railway Stations, &c.

Force Pumps on Railway.

Wrought-iron Portable Pumps.

Patent Centrifugal Pumps, for Contractors use, or Irrigation Work.

Cast-iron House or Garden Pump.

Portable Injectors for Steam or Water Power.

Melbourne, 1880.

1879.

Cincinnati, June, 1880

OVER 450,000 FEET SOLD DURING 1881.

Including 3,877 feet of main Driving Belts, of widths ranging from 13 in. to 60 in., are working in over 6,000 Mills and Works in Europe and America.

The following Tests (by Kirkcaldy, of London) show the relative strength and value, compared with Leather.

| | Breaking Strain per Square Inch of Section. | Price per foot. |
|-----------------------------------|---|-----------------|
| Best Double Leather 6 in. Belting | 3,572 lbs. | 8s. 7d. |
| Gandy's 6 in. x 3-ply Cotton | 6,811 lbs. | 2s. 6d. |

THE GANDY BELT.

Any Length or Width for Main Driving.

It is the best belt ever made for all purposes. Much Cheaper and Stronger than Leather. Thoroughly Waterproof, and not affected by temperature, clings well to the pulleys, runs true, and can be made any length without joints.

This Series of Belting (see engraving) was supplied in One Order to Messrs. John Crossley and Sons, Halifax, May 1, 1880, and continues to give entire satisfaction.

THE "GANDY" BELT.

Gandy's Patent American Cotton Belting, can claim a superiority over leather belts in every particular; its cost being about half that of leather, while its strength and gripping power is about double that of the best leather. As shown by repeated tests taken by Kirkcaldy, of London. These tests are given above, to which special attention is directed. These "Gandy" Belts are made of any width up to 72 inches, and any length up to 340 feet without joint, thus obviating the necessity of having two belts on the same pulley, a system of driving which is never satisfactory, as it is impossible to have belts of exactly the same tension; hence one or the other is always causing a stoppage. These stoppages are avoided by using Gandy's Patent Belts in one width. These Gandy Belts are made of the finest American Cotton Duck, specially prepared at Baltimore for the purpose, and then put together and finished by Gandy's patented special Machinery, and process to prevent stretching, and render them impervious to atmospheric influence. Possessed of advantages such as these, the universal adoption of Gandy's Belts can only be a question of time.

A SUBSTANTIAL GUARANTEE GIVEN WITH EVERY MAIN DRIVING BELT.

HEALTH, STRENGTH, AND ENERGY.

DR. LALOR'S PHOSPHODYNE.

(Trade Mark—Phosphodyne.)

TWENTY YEARS' PUBLIC TEST, AND THOUSANDS OF TESTIMONIALS FROM

ALL PARTS OF THE WORLD ESTABLISH

PHOSPHODYNE

as the only Safe, Reliable, and Never-failing Phosphoric Remedy for Over-worked Brain, Sleeplessness, Harassing Dreams, Worry, Anxiety, Excitement, Epilepsy, Business Pressure, Wasting Diseases, Nervous Prostration, Stomach and Liver Complaints, Impoverished Blood, Premature Decay, and all morbid conditions of the system dependent upon the deficiency of the Vital Forces.

DR. LALOR'S PHOSPHODYNE PURIFIES AND

Enriches the Blood, Clears the Skin, thoroughly Invigorates the Brain, Nerves and Muscles, Re-energises the Failing Functions of Life by supplying the PHOSPHORIC element which has been wasted, and thus imparts Energy and Fresh Vitality to the Exhausted Nerve-Electric Force, and rapidly Cures every form of Nervous Debility, Paralysis, Kidney, Nervous, Mind, and Heart Diseases, from whatever cause.

This elegant Phosphatic combination, the Wonder of Modern Chemistry, is pronounced by the most eminent members of the Medical Profession to be unequalled for its power in replenishing and elaborating the Vitality of the Body; by its supplying all the essential and vitalising constituents of the BLOOD, BRAIN, and NERVE SUBSTANCE; and for developing all the Powers and Functions of the System to the highest degree; by its being agreeable to the palate, and innocent in its action. While retaining its wonderful properties, it acts as a Specific, surpassing all the known THERAPEUTIC AGENTS of the PRESENT AGE, for the SPEEDY and PERMANENT CURE of the above disease.

DR. LALOR'S PHOSPHODYNE is sold in Bottles at 4s. 6d. and 11s. by all Export, Wholesale, and Retail Medicine Vendors throughout the World.

IMPORTANT NOTICE—NONE IS GENUINE UNLESS the name, Dr. Lalor's Phosphodyne, London, England, is blown in the Glass of each Bottle, and every Bottle bears the British Government Stamp, with the words DR. LALOR'S PHOSPHODYNE, London, England, engraved thereon by Order of her Majesty's Honourable Commissioners; IF NOT, IT IS A FORGERY, AND YOU HAVE BEEN IMPOSED UPON BY A WORTHLESS IMITATION.

MANUFACTURED ONLY AT THE

PHOSPHODYNE LABORATORY BY

DR. ROBERT D. LALOR,

BAY HOUSE, 32, GALSFORD-STREET, LONDON, N. W.

PHOENIX IRON WORKS, CALCUTTA.

THE OLDEST ENGINEERING ESTABLISHMENT IN INDIA, JESSOP & CO.,

**Civil and Mechanical Engineers, Contractors, Brass and Iron Founders,
Metal Merchants, &c.**

*Forged and Cast Iron Work, Boilers, Machinery for Jute, Cotton and Rice Mills, Collieries, Indigo Concerns, Tea Gardens, &c.,
Contractors' and Brick-making Plant, and every class of Iron and Brass Work made to order.*

SOLE AGENTS FOR

Robey & Co's celebrated Portable and Fixed Engines and Machinery, Gwynne & Co's "Invincible" Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

IMPORTERS AND MANUFACTURERS OF EVERY DESCRIPTION OF STEAM ENGINES AND MACHINERY.

Robey & Co's Portable, Horizontal, Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand, Lift and Force Pumps, Tangye's "Special" Steam Pumps, "Vauxhall" Donkey Pumps, Flour Mills, Sookkee Mills, Pug Mills, Brick-making Machines, Road Rollers, Saw Benches, Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines, Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selkirk's Boiler Tube Benders, Steam Pressure Recorders, Electric Pens, Richard's Engine Indicator, Gifford's Injectors, Cooking Stoves, Fire-Proof Safes.

The following are the principal advantages of the "Invincible" Pump :—

1st.—It is arranged to swivel on the bed plate, and may be placed at any angle simply by slackening a few nuts, without interfering in any way with the bed plate or the joints of either the suction or discharge pipes.

2nd.—It does not require a foot valve, being fitted with small air exhauster and check on discharge which always keep the pump charged ready for work.

3rd.—The bearings are made on an entirely new principle, and one bearing will last out four of the old arrangements.

**J. & H. GWYNNE'S
"Invincible" Centrifugal Pump.**

4th.—The form of the pump casing is so arranged that one side can be taken off in a few minutes for the inspection of the whole of the disc and interior of the pump.

5th.—Hand holes are made on each side of the suction pipes to enable any foreign matter which may get into the pump or disc to be easily removed. The covers are fitted with a bayonet joint so that they can be removed and replaced in less than a minute.

6th.—The "Invincible" is 25 per cent lighter than any other Centrifugal Pump in the market, and discharges at least 10 per cent. more water for the power applied.

Ransome's Indian Plough. Price, Rs. 15.

Howard's Ryots' Plough. Price, Rs. 10.

These Ploughs have been expressly designed and manufactured for the use of the Ryots of India, whose special needs have been carefully studied in their construction. They embody all the qualifications for which the native-made implements have hitherto been preferred, whilst being incomparably superior in strength, durability, and efficiency.

MORAE'S PATENT SUB-SOIL AND GENERAL PLOUGH

Stirs up the soil to three times the depth of a native plough, and leaves the good mould on the top. Goes through the dirtiest land without getting choked with weeds. Price, Rs. 15.

INDIGO AND TEA PLANTERS' IMPLEMENTS AND STORES.

ENGINEERS' TOOLS AND STORES OF ALL KINDS.

ALWAYS ON HAND A LARGE STOCK OF PLATE, BAR, ANGLE, TEE AND CORRUGATED IRON, STEEL, BRASS, COPPER, PIG IRON, FOUNDRY COKE, SMITHY COAL, FIRE BRICKS, AND FIRE CLAY.

NOTICE.

SUBSCRIBERS to the *STATESMAN, FRIEND OF INDIA*, and *INDIAN AGRICULTURIST* are informed that arrangements have now been made by which these journals will for the future be published under the general superintendence of the undersigned.

All communications concerning the general business of the *STATESMAN AND FRIEND OF INDIA* Office, Advertisements, and Subscriptions to the daily *STATESMAN AND FRIEND OF INDIA*, weekly *FRIEND OF INDIA* AND *STATESMAN*, and *INDIAN AGRICULTURIST*, should be addressed to the **MANAGER**.

All communications regarding literary matter should be addressed to the **EDITOR** of the paper for which it is intended.

WILLIAM RIACH.

June 15th, 1881.

Report of the Director of Public Instruction, Bombay Presidency.

CORRESPONDENCE.

CAWNPORE FARM EXPERIMENTS.

TO THE EDITOR.

SIR,—In the February number of your paper a contributor, J.P.P., gives some startling deductions from the figures in Mr. Fuller's recent report on the Cawnpore Farm experiments, and arrives at the conclusion that the soil sample, of which Mr. Fuller publishes an analysis, must either have been artificially enriched with nitre and wood ashes before transmission to Roorkee, or the Roorkee chemist must have made an erroneous analysis. In justice to "the Roorkee chemist," Dr. Murray Thomson, allow me to point out that he had nothing to do with the analysis. The sample of soil was collected by Mr. Fuller himself, and sent direct to me; consequently we alone are responsible for any error that may be discovered in the results.

To support the wood-ashes theory, your contributor makes a curious calculation, from which it appears that, according to the analysis, there must have been nearly 4,000 pounds of free potash in the upper three inches of every acre of soil. In the published analysis there is nothing whatever to suggest the presence of any free alkali in the soil, and if J.P.P. will take the trouble to look at the figures again, he will see that the potash, on which his calculation is founded, was contained in the hydrochloric acid extract, and was therefore probably derived (except so much of it as was contained in nitre) from the zoölitic constituents of the soil, which are decomposed at once by hydrochloric acid, but yield very slowly to the action of the acids in the soil. At once, therefore, more than half the total of saline constituents made out by J.P.P. is shown to have no existence, and the total would not look so great as it does if the results were shown all through in pounds instead of grains. If J.P.P. will take the trouble to go over his calculation again, he will find that in the portion a foot square and an inch deep, which he takes, there is only 0.027 lb. of nitre (supposed to be potassium nitrate), since the soil contains all parts of anhydrous nitre acid in 10,000, and its specific gravity is about 2.54. Whether wheat would germinate in such a soil, or not, I do not know; there is no apparent reason why it should not, but at all events, nobody expects it to do so. The soil sample was collected in the hot weather after the reaping of the rabi crop, when, for upwards of six months, capillary attraction and evaporation had been concentrating soluble salts in the surface layers. At the end of the rains, when wheat is sown, these salts have been washed down, and disseminated through a depth of perhaps ten or fifteen feet, and if this sample had been collected at that season, it would probably not have shown a twentieth part of the proportion of soluble salts found in it in the hot weather.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parentheses, or in a foot-note. The bigha in particular varies so much in the different provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

The percentage of anhydrous nitric acid found in this soil is doubtless much greater than is usually met with in cold countries, where the nitrogen of the soil exists chiefly in organic combination and in the form of ammonia. Thus, Mr. Robert Warington (*Journal of the Chemical Society* for August, 1882) finds that the upper nine inches of the air-dried soil of Sir J. B. Lawes' experimental farm at Rothamsted contains on the average only 6.77 parts of oxidized nitrogen per million—a quantity which looks exceedingly minute in comparison with the 235 parts found in the surface layers of the Cawnpore soil after six months' concentration by evaporation. But then the drainage water at Rothamsted actually carries off in the course of a year more nitrates than are ever present in the upper nine inches of soil at any given time. On the mean of the six years, 1877-82, the loss of oxidized nitrogen in the drainage water amounted to 20.17 kilogrammes per acre, or 7.14 grains for every square foot of surface. Taking the specific gravity of the soil at 2.5, the weight of a block a foot square and nine inches deep would be about 820,800 grains. Hence, since nitrification goes on chiefly at the surface, 8.7 parts of oxidized nitrogen are removed from every million of surface soil while the soil contains only 6.77 parts at any instant of time.

It is evident, therefore, that the nitrates of Indian soils, in which there is no subsoil drainage, should not be compared with the minute and fugitive proportion of nitrates found in England, but with the whole of the nitrogenous constituents of the English soil, since Indian soils like that at Cawnpore contain practically no ammonia and no organic nitrogen. Compared in this way with any average wheat soil of Europe that of the Cawnpore farms shows to great disadvantage.

Those who know most about agricultural chemistry put the least trust in the results of analysis, however carefully performed, as a measure of fertility of a soil. To begin with, much depends on the conditions under which the sample is taken, the quantity of soluble salts near the surface, after a prolonged drought, differing enormously, for example, from that found after heavy rain. Then the chemist is quite unable to reproduce in his laboratory the conditions of the field or anything approximating to them, time alone being a most important condition which has to be disregarded. The quantities of potash, lime, &c., found in a hydrochloric acid extract probably represent fairly enough the total ultimate fertility of the soil in these constituents; but while the chemist gets them into solution in an hour, they may require centuries for solution in the field, and while they remain in insoluble minerals they are useless to plants. Again, this very determination of nitrates, which J.P.P. treats so lightly, is so difficult (proportion being so minute) that in a soil analysis it used never to be, and is now hardly ever attempted. The best chemists find it very difficult to agree about the process which gives the most exact results, while different methods in the same hands, and those the most skilful, give results which often differ by 50 or 100 per cent. An analysis, in short, may be appended as this has been by Mr. Fuller, to confirm the results of field experiments, but by itself it means very little.

Mr. Fuller has committed the mistake in inductive logic of basing a wide generalization upon a very limited breadth of experience. His remarks may be understood to imply that in all Indian soils, and for all crops, nitrogenous manures are the most valuable; whereas, all that may be legitimately inferred from his admirably conducted experiments, is that on the experimental plots of the Cawnpore farm, in their present condition, the manure most required for a wheat crop is a nitrogenous one—the manure most required for a different crop on the same ground, or for wheat in another part of India, might be a very different one.

BOOKS ON AGRICULTURAL CHEMISTRY.

TO THE EDITOR.

SIR,—Besides the books on Agricultural Chemistry, mentioned in your issue of February 1883, I would recommend the following ones to your correspondent, Baboo Rasik Behari Biswas:—

- Agricultural Chemistry, by Davis.
- Familiar Letters on Chemistry, by Liebig.
- Soil, Manure, and Plant, by Schrottky.
- Soils and Manures, by John Donaldson.
- Chemistry of Agriculture, by Arthur Henry.
- Liebig's Letters on Agriculture.
- Agricultural Chemistry, by Boussingault.

J. N. B.

Choodanga, K. B. Railway, 4th February 1883.

CASTOR-OIL SEED.

TO THE EDITOR.

SIR,—Can you or any of your readers kindly inform me where I could get a small or large quantity of really good and productive castor-oil tree seed? I shall be glad to pay for the same. I would also be glad to know where good silkworm-eggs and mulberry cuttings could be got.

CULTIVATOR.

Moolydhur, T. G., 30th January, 1883.

JUTE.

TO THE EDITOR.

SIR,—As a contributor to the *Farmers' Review* on flax culture and free trade questions connected with the fibre industry in the Western States of the Union, I herewith take the liberty of requesting you will kindly procure and send me the cost of production and preparation of jute, including all expenses until placed on board-ship.

For some years back attempts have been made in the Gulf and Southern States, Mississippi, Louisiana, Florida and others, to cultivate jute, which appears to be perfectly well adapted to the soil and climate of those States. It is asserted, however, by the protectionists of this country, that the cultivation of jute can only be made remunerative to the American planter, if the native production is "protected" by a high duty, on account of the so-called pauper labour in India, which they assert is, according to their various statements, 20, 15, and even 10 cents a day. In order, therefore, to enable me to judge in how far those statements are correct, and their claim for a high protective duty justified, you would greatly oblige me by sending me a detailed statement of the cost of cultivation of say 50 or 100 acres of jute, so that a correct comparison may be made with what it costs in this country to produce jute. It would of course be interesting to know also what is the price of the seed, and the quantity sown per acre, the cost of rotting, breaking, &c., also the quantity produced per acre: in fact, all the details necessary in order to go to the root of the matter.

H. KOELKENBECK.

Chicago, 15th December 1882.

NOTE.—Perhaps some of our readers may be kind enough to favour us with the details asked for by our correspondent.—ED., I. A.

The Indian Agriculturist.

CALCUTTA, MARCH 1, 1883.

FOREST ADMINISTRATION IN THE PUNJAB.

THE report on Forest Administration in the Punjab for the year 1881-82 shows that a good deal of useful work was done during that period. The changes in the area under the management of the Forest Department, which took place during the year under report, were as follows:—

| | SQUARE MILES. | | | |
|-----------------------------|-------------------|--------------------|---------------------|--------|
| | Reserved Forests. | Protected Forests. | Unreserved Forests. | Total. |
| Area on the 1st April 1881 | 049 | 311 | 3,560 | 4,914 |
| Excluded during the year | ... | ... | 238 | 238 |
| Added during the year | 217 | ... | 1 | 218 |
| Area on the 31st March 1882 | 1,160 | 311 | 3,799 | 5,270 |

The addition of 217 square miles to the area under reserved forests occurred in the Jhelum and Mooltan divisions, with the exception of 9 square miles in the Chamba

division. The classification of the reserves, as it stood at the end of the year, was as follows:—

| | Square Miles. |
|--|---------------|
| Upper Hill Forests (deodar, &c.) | 545 |
| Lower Hill Forests (chil, &c.) | 110 |
| Plains Forests, <i>rakhs</i> (sacchar, jhand, &c.) | 506 |
| Total | 1,160 |

There has been no change in the area under protected forests during the year under notice; but we observe that it is ~~planned~~ to declare the Kulu forests and the Lahore *rakhs* as protected areas. The 311 square miles which are at present declared "Protected Forests" are—

| | Square Miles. |
|--|---------------|
| The Kala Chitta, in Rawul Pindas, area | 171 |
| The Gujranwala <i>rakhs</i> | 140 |

The local Government notices with satisfaction that there has been a considerable decrease during the year of prosecutions for breaches of the forest rules. The number of cases for trial amounted to 846; of these, 136 cases belonged to the year preceding, so that the new prosecutions for the year 1881-82 were 710. Of the total of 846 cases to be disposed of, 716 were concluded during the year, 515 of which resulted in convictions, and 201 in acquittals. The prosecutions were chiefly on account of the following offences:—injury to forests by fire, unauthorised felling, or appropriation of wood, or minor produce, and grazing without permission. There were 92 fires reported in the forests under the control of the department; the area burnt was 15,633 acres, against 142,599 acres in 1879-80, and 22,073 acres in 1880-81.

As regards cultural operations, the following were the most important of the year:—

Sowing of 20 acres at Sathu with chil (*pinus longifolia*).

Re-sowing of 200 acres in the public reserve.

Planting of 8,425 deodar seedlings at Kalatop on the Ravi side (Chumba division).

Sowing and planting out of 90 acres in Kulu with deodar.

Sowing of 206 acres in Bashahr with deodar.

These operations are all reported as having been successful. The experiments in the cultivation of European and foreign trees have given satisfactory results. Spanish chestnuts at Kilba and Nachan; cork, oaks, and olive trees in Kulu; limes, maples, elms, larches, the Lombardy poplar, Tasmanian blue-gum in Kulu—are all reported to be doing well.

The timber operations of these departments during the year under report were conducted on a larger scale than in the year preceding, as will be seen from the following figures:—

| | 1880-82. Cubic feet. | 1881-82. Cubic feet. | Increase. Cubic feet. |
|----------------------------------|-------------------------|-------------------------|--------------------------|
| Timbers received during the year | 496,676 | 543,405 | 46,729 |
| Timber sold during the year | 476,208 | 578,940 | 102,732 |

The quantity of timber imported into British territory, compared with the results of the previous year, is as follows:—

| | 1880-81. No. | 1881-82. No. |
|-------------|-----------------|-----------------|
| Deodar logs | 46,946 | 20,434 |
| Pine logs | 7,336 | 2,955 |
| Sleepers | 270,021 | 307,929 |

The deodar logs were all imported from Cashmere, and by far the greater portion of the pine logs were also obtained from Cashmere. The 307,929 sleepers were imported from Cashmere, Mandi, Kapurthulla, and other native states.

The balance of timber in the depôts at the close of the year consisted of 24,986 logs and pieces, containing 110,034 cubic feet. We see that the scarcity of firewood at Rawul Pindas has been brought to an end by the opening of the railway, which tapped the fuel supply of Attock, and the sales from the Government depôt have thereby fallen below those of the preceding year by 50,000 maunds. The Punjab Government considers this satisfactory, inasmuch as the resources of the *rakhs* in the neighbourhood of Rawul Pindas were in some danger of exhaustion under the pressure of great demand. It is also stated that there was a large falling off also in the amount of fire-wood removed by purchasers in the *Wootan rakhs*, as the railway

contractors were able to arrange with private persons for the supply of fuel on favorable terms.

We see that the financial results of the working of the Department are considered to have been satisfactory. The revenue realised was Rs. 16,629 more than in 1880-81, but as the expenditure increased by Rs. 20,902, the net income was Rs. 4,273 less than in the previous year, and amounted to Rs. 1,32,038.

We observe that, in accordance with the wishes of the Government of India, an experiment is being tried in utilising the services of well-recommended non-commissioned officers of the native army, and during the year two men were appointed to the subordinate staff of the Forest Department, and a third is about to be offered the appointment of forester in the Department.

THE COTTON CROP IN THE MADRAS PRESIDENCY.

FROM the report on the cultivation of and trade in cotton in the Madras presidency for the year 1881-82 (Fussli 1291), it appears that the season was generally more favorable than in the preceding year in most of the districts in which cotton is extensively grown.

The area under cotton cultivation during the year amounted to 1,653,595 acres, against 1,508,226 in 1880-81, or an increase of 145,369 acres over the area of the year preceding. The increase took place chiefly in Bellary and Tinnevely, and to some extent, also, in Cuddapah and Coimbatore. From a comparison of the figures for the last six years, we observe that since 1877-78—the year of the Madras famine—the cultivation of cotton has been steadily increasing, and that the area now reached stands on a level with that of the year immediately preceding the famine, when it amounted to 1,645,389 acres.

The cotton grown was of the indigenous kind, of which there are two species in the presidency, called the white and the red from the color of the flowers. One is a six-months' crop, and the other twelve months. We observe that the acclimatised Bourbon cotton was cultivated in Coimbatore on an area covering 64,731 acres or a little over one-fourth of the total extent under cotton in the district, and yielded 28,898 cwts. of cleaned cotton, or about 50lb. per acre against 26lb., the estimated yield of the indigenous species. Experiments were also made in the Bellary district during the year with Hingunghat, Dhollera, Broach and Bourbon seeds. Broach and Dhollera proved a success, but the results of the attempts made with the Hingunghat and Bourbon seeds is not given.

The total outturn of cleaned cotton during the year amounted to 493,643 cwts., valued at Rs. 1,05,76,044, as against 431,071 cwts., valued at Rs. 97,29,575, in the year preceding. The average yield per acre ranges from 19lb. in Anantapore to 54lb. in Vizagapatam. For the whole presidency the average yield was 37lb. per district, against 36lb. in 1880-81. The largest outturns of cotton were obtained in the Tinnevely, Kistna, Coimbatore, Kurnool, Madura, Cuddapah, Bellary, and Anantapore districts.

The cost of cultivation per acre varied from Rs. 2-14-0 in Kurnool to Rs. 11-14-11 in Vizagapatam. Comparing the cost of cultivation per acre with the value of the average yield per acre of cleaned cotton, calculated at annas 3-6 per lb., it would appear that in several districts the cultivators must have lost heavily. The districts in which the average cost per acre exceeded the value of the average yield per acre are as follow:—

| District. | Average cost per acre. | | | Value of average yield per acre at 36 annas per lb. | | |
|--------------|------------------------|----|----|---|----|----|
| | R. | A. | P. | R. | A. | P. |
| South Arcot | 10 | 9 | 1 | 5 | 11 | 0 |
| Coimbatore | 11 | 11 | 0 | 7 | 7 | 0 |
| Madura | 9 | 15 | 8 | 8 | 15 | 6 |
| Salem | 10 | 14 | 0 | 10 | 8 | 0 |
| Tanjore | 10 | 7 | 9 | 9 | 10 | 0 |
| Tinnevely | 9 | 7 | 10 | 7 | 10 | 6 |
| Trichinopoly | 9 | 7 | 9 | 5 | 4 | 0 |

The Madras Board of Revenue, however, do not appear to place much trust in these figures, and again impress upon collectors the necessity of testing the accuracy of the information furnished by tahsildars. The several items

which make up the cost of cultivation in each district are—(1) value of seed, (2) cost of ploughing, (3) cost of fencing, (4) manure, (5) cost of sowing, (6) cost of weeding, (7) hire for gathering, (8) assessment per acre. The cost of ploughing appears to have been the heaviest item in several of the districts, and ranged from Rs. 1-1-0 in Vizagapatam to Rs. 4-12-8 in Tanjore, though in the latter it included also the cost of fencing.

The average retail prices of cotton retained for local consumption during the year varied from Rs. 85 per candy of 500 lb. in Madura, to Rs. 130 in Salem. Compared with 1880-81 the prices obtained were on the whole more favorable.

The total quantity of raw cotton exported from the presidency during the year under report was 459,351 cwts., against 509,889 cwts. in 1879-80, and 365,887 in 1880-81. Compared with the past year, therefore, the exports show an increase of 96,464 cwts., and this is said to be chiefly due to heavy shipments made to the United Kingdom from Tuticorin and Madras during the months of April and June 1882, owing to the very active demand that prevailed in the English market at this time and to the rise in the price of the articles. Of the total exports of the year, 422,346 cwts. was taken by foreign countries, the largest shipments being to the United Kingdom, Italy, France, Austria and Spain; of the balance, 37,894 cwts. went to Bombay, and 9,111 cwts. was exported to Bengal. The total value of the exports was Rs. 1,11,61,394, as against Rs. 92,19,371 in 1880-81.

It would appear that the condition of the weaving classes in the presidency has been gradually deteriorating from the combined effects of the famine and increased importation of English piece-goods. During the year under report the total number of weavers is stated to have been 345,818, against 307,702 in the year preceding. Although in a few localities cloths of very superior quality are still made, which are purchased chiefly by the richer classes in preference to English piece-goods on account of their great durability, the manufacture is stated to be now principally confined to inferior cloths, country twist being used for the coarser kinds, and English twist for the better sorts.

The three cotton mills in the presidency—the Southern India Spinning and Weaving Company, the Madras United Spinning and Weaving Company, and the Buckingham Mills Company—are stated to have continued working throughout the year. The quantity of cotton taken by them was 59,818 cwts., which was chiefly obtained from the Coimbatore, Trichinopoly, Cuddapah, and Bellary districts, at prices varying from 3 annas to 3 annas 7 pies per lb. The Southern India and the Madras United turn out only twists, and the Buckingham Mills produce only yarns.

THE COLONIZATION OF THE TAVOY.

IT has been urged, from different points of view, that the requirement of the times, in an acknowledged period of agricultural depression, is the establishment of agricultural banks by private enterprise for money advances to the peasantry; and in these columns necessity for an improved condition in the ryots' relations with the zemindar has been treated of lengthily. But the circumstances of the European planting community afford equal occasion for anxious consideration. Whatever the divergence in the commercial aspects of the two great industries in India proper, i.e., of tea and indigo, it is certain that the price paid by the consumer of the first is extravagantly out of proportion to the profits derived by the producer, and it is questionable whether the remedy for this is only to be contrived by an extended sale in new markets; and, with regard to the latter, the greatly increased cost of manufacture within the last few years, and the difficulties concerned with the land and rates for labour, largely take from the remunerative return of indigo, while it may be roundly asserted that both industries have the common misfortune of being overcrowded. Every indigo concern has an excess of European employees, and the excess in the tea gardens noticeably lessens the number of unemployed men who are to be found in the streets of Calcutta. These men are distinctively a class without the reproach of improvidence, for their portion has been cast in poorly

salaried appointments, and the too ready surmise of intemperate habits is an undeserved libel on the majority. Every ounce of tea, every cake of indigo finds disposal in the market, and the question whether the tea-planter can not participate to a greater degree in the high prices paid by the consumer will demand attention as the opening up of new markets is effected, the result of which will be to maintain the high retail prices without appreciable gain to the producer. But though, of course, the intermediary agency is the occasion of this, that agency is the backbone of the planter; it provides working advances, it looks in bad seasons, and is concerned with the entire realization. It is not therefore that in this generalization of the circumstances of tea enterprise any aspersion is levelled at the agencies which, in the eminent firms of Messrs. Moran and Thomas, find distinguished reputations. It is the general want of independent capital which characterizes the enterprise that has to make a return on borrowed money. This must continue until the concerns grow wealthy by economic management, good seasons, and large sales. But the unemployed excess of planters,—what is to be done by them? Emigrate. Where to? With what means? That pioneer spirit of enterprise which has built up the vast fabric of the Indian Empire has made no response to the invitation of the Government of British Burmah, to colonise the district of Tavoy. That Government has proffered rent-free grants of land on the most liberal terms. The country itself is primeval forest and virgin soil, with a mountain range of 6,000 feet altitude. The climate is pleasant, and the two hottest months of the year, February and March, are cooled by the sea breezes. It has been described by Dr. Hoffer, an American missionary, in 1838, as an Eden of fertility, and the "Imperial Gazetteer of India" gives an authoritative corroboration of its untried capabilities. Sparsity of inhabitants has presented a labour difficulty; but this may be said to have existed in the past, and the present time affords the opportunity of attracting Chinese labour with peculiar facility. Shut out from America and Australia, Chinese emigrants are making their way to North Borneo. The Cingalese incursion into Queensland has proved abortive. There are masses of labourers to be had when the stream is once directed. But the requirement is capital. Planters out at elbow may proffer their services, in preference to attempting the Colonies; and such as have an insignificant trifle may well hesitate before embarking their little all in a venture to Tavoy, where the first reverse would prove ruin. But the avidity with which shares in the North Borneo Company have been taken up shows that the dubious nature of foreign investments has led the public to seize upon any other outlet for speculation that gives fairer promise. Money cannot be tied up, and English capital may be as confidently directed to the colonisation of Tavoy as to possibilities in North Borneo. A project is, we understand, under the consideration of Mr. Hudson, the Secretary of the Behar Planters' Association, which has not yet proceeded beyond a preliminary enquiry, as to its general merits, and the Government of British Burmah favours the formation of a company, which would have for its objects the acquisition of the entire available land, and planting operations on a large scale. Here is a scheme which, if practicable, should receive, and there is no doubt will receive, the encouragement of the Government of India. Not less politically, than commercially, will advantage be derived from the opening out of a tract which is the high road to Bangkok and Siam.

MR. BRANDIS' SUGGESTIONS REGARDING FOREST ADMINISTRATION IN MADRAS.

IT is scarcely possible within the limits of a single article to do anything like justice to the very full and able "Suggestions regarding Forest Administration in the Madras Presidency," by Mr. D. Brandis, F.R.S., C.S.I., the Inspector-General of Forests to the Government of India. We have no hesitation in stating that Mr. Brandis' "Suggestions," as he modestly calls them, form the most complete report on Indian Forestry that has, up to the present, been issued by the Government Press of any Presidency. The work consists of 337

pages folio, and deals with the whole subject of forest administration in such an exhaustive fashion, that it will probably for many years to come remain the highest authority on the subject with which it deals. Mr. Brandis is, after a long career in India, about to retire from the service, so that the present volume may be regarded as the last official contribution to Indian Forestry he is likely to make. The opinions of a man of such wide and varied experience and attainments with them a weight of authority which is on the whole likely to shape, for some considerable time at least, the policy of the great department over which he so ably presided. A work of this nature, so varied in its contents, so multitudinous in detail, so carefully thought out in all its parts, and so fruitful in suggestions, is not easily dealt with when any attempt is made to present in anything like adequate detail the topics with which it deals. Mr. Brandis' "Suggestions" are full of material from which not only forest officers and the official classes generally may gather useful information and suggestions, but the wealth of subsidiary collateral topics dealt with are such, that nearly every educated man in India may read with pleasure and profit what Mr. Brandis modestly says, was mainly "intended to be read by the forest officers employed in the districts to which the remarks relate."

All we shall on the present occasion venture to do, is to present to our readers some of Mr. Brandis' conclusions, reserving for a future occasion a more detailed examination of the "Suggestions." With regard to the supply of railway fuel, he says that—

"The railway should be encouraged to draw as much wood as possible from private forests; the supplies from this source in the inland districts will probably diminish, and as they diminish, the requirements must be met to a greater extent from the Government forests. In order to make my meaning clear, I have, in the preceding paragraphs, put forward some figures, which may be summarised as follows:—

| | Private. | Government. | Total. |
|----------------|----------|-------------|--------|
| | Tons. | Tons. | Tons. |
| Supply in 1881 | 55,760 | 12,660 | 68,420 |
| Future supply | 39,000 | 42,000 | 81,000 |

"Should the efforts fail, which must be made to induce private landholders to preserve and plant with the view of supplying the railway, the supplies from private sources would probably diminish further; but as they decrease, the condition of the Government forests will improve, and consequently their productive powers will increase. This relates to the inland districts. On the east coast the private casuarina plantations are so extensive, chiefly in Chingleput, that the price of this wood must fall, and it may eventually pay the Madras Railway to burn it.

"Should the extensions here suggested be found to be insufficient to supply the requirements of the railway, the further experience which will then have been gained will doubtless show the way to the measures required to meet the case. The Kurnool-Cuddapah canal is navigable from August to January, and the question should be studied in detail, whether wood from the Nallamais in Kurnool and the Lankamalais in Cuddapah can be brought down the canal to Krishnapuram on the railway at remunerative rates. The floating of wood down the Cauvery has been tried and been found to fail, but plantations near the line in the vicinity of the Cauvery or other rivers might be made; the former reserves near Mettapollium might be re-established, or suitable tracts on the Nilgiri slopes, near the Mettapollium terminus, might be placed under strict protection. If a railway is constructed to Ootacamund, the plantations of Australian *eucalyptus* and *acacia* on the plateau should be extended largely and might furnish a large supply. So much has been established by the researches recently made by Mr. Hutchins, that these plantations can be made to furnish a mean annual yield of 6 tons per acre, good and bad included. Under these circumstances, it is not at all impossible that, if these plantations can be made and main-

tained at a responsible outlay, and if the needful land can be obtained, the blue gum grown on the Nilgiris may some day contribute to the fuel-supply of the Madras Railway. If suitable land can be made available on the plateau of the Shevaroy, an experimental plantation of Australian trees should be made. *Acacia aelanoxylon* as well as some species of *eucalyptus* seem to thrive at Yercaud. At present it would be premature to enter further into these schemes. It will be time enough to consider them when necessity arises for doing so. It has been recommended to encourage the use of coal in the place of wood on the Madras Railway, in order to guard against the destruction of the forests. Such recommendations are not based upon a correct appreciation of the case. In the interests of forest conservancy, it is most desirable to encourage the consumption of wood by the railway. Forests are useful in many ways, besides producing a supply of wood and timber. But forests cannot be maintained without some return of revenue from them. Thus, if the Madras Railway finds it profitable to burn wood in preference to coal, this will cause an increased demand for wood, which will enable Government to maintain, under efficient protection, a larger area of State forests than would be possible if the produce could not be sold.

"In the preceding remarks I have not adverted to Indian coal as a possible rival of wood-fuel. It is not impossible that when the system of coast canals has been completed from the Hooghly to Madras, or perhaps even sooner, Bengal coal may compete at Madras with English and Australian coal. And when the coal-fields in the Nizam's territory have been connected by tramway with Bezvada on the Kistna river, it is probable that Singareni coal may be delivered at less cost at Madras than sea-borne coal. But considering the quality of the Singareni coal, and the large quantity of ash which it contains, it seems doubtful whether, under existing circumstances, it can be landed at Madras at rates sufficiently low to enable the railways to dispense with wood-fuel in the inland districts of the Presidency."

The wealth of the Madras Presidency in workable iron ores is well-known, and there still exists at all events the remains of the old iron industry of the province. Unlike Bengal, Madras has no coal, so that the future of iron smelting in Madras is entirely a forest question. The cost of sea-borne coal, it seems, ranges from Rs. 16 to Rs. 18 a ton at the eastern ports, and is consequently prohibitive; nor does it seem likely that Indian coal from Bengal, the Nizam's dominions, or Central India could be delivered at rates sufficiently low as would make it available for iron-smelting in inland districts. It is, therefore, to the forests of the Presidency that Government must look for whatever local iron industries it may be possible to build up, and foster. On this point Mr. Brandis says:—

"Under proper management, the extension of iron-smelting in the Madras Presidency will in no way increase the denudation of the country. On the contrary it will facilitate the formation, protection, and improvement of the forests.

"In most forests the more valuable species, the timber or other produce of which finds a ready sale even when brought from remote localities, is associated with a large proportion of the less valuable kinds, for the produce of which there is no demand in such places. The less valuable species profit equally with and in some cases more than the valuable kinds, by efficient protection, and particularly by protection against fire. In fire-protected blocks, the forest becomes dense and thick, the grassy glades and other blank spaces fill up rapidly, but a large proportion of the material which grows up in so satisfactory a manner cannot be utilized. On the contrary, its existence in the forest prevents the free production of the more valuable kind, which therefore cannot be cut as freely as would otherwise be desirable. The abundance of inferior classes of wood will, therefore, be felt as a burden and a source of difficulty hereafter, when a rational plan of working is set on foot. The native iron-smelters give preference to certain kinds of wood, such as *acacia catechu* and *albizia amara*, but the charcoal of most species, both of the deciduous and the evergreen forests,

can be utilized for iron-smelting. I may here mention that Colonel Kestinge, when Political Agent of Nimar, before 1857, found that the light and soft wood of *boscellia thurifera* (saler) made excellent charcoal for iron-smelting in the works established by him in Nimar, and successfully worked during a series of years with the aid of a Swedish iron-master.

"The extension of iron-making by means of charcoal will be a great help towards the development of rational forest management in the Madras Presidency. But the native methods of iron-smelting with charcoal are exceedingly wasteful, and an attempt should therefore be made to introduce an improved method. It is at present generally supposed that the direct system of producing wrought iron from the ore is not capable of considerable improvement. This is a point upon which I am not competent to form any definite opinion. I know, however, that some persons in England competent to speak on the subject hold that the direct process is capable of considerable improvement, and that iron-smelting by means of charcoal in India has a great future before it.

"Moreover, it may not be impossible to carry out a suggestion made some time ago by Dr. H. Warth, Professor of Natural Sciences at the Dehra Doon Forest School, and to construct blast furnaces of a somewhat smaller size than those used in Europe, so that they can be managed by natives. The object would be to teach them the system of making pig-iron first, and converting this by a separate process into finished iron. Such experiments can only be made by Government agency, and I am of opinion that it will be well worth while to attach a competent metallurgist, who has had a practical experience in iron-smelting with charcoal, to the Madras Forest Department for a series of years—first, in order to assist the Forest Officers in the selection of reserves in the iron districts; and afterwards to undertake iron-making in suitable localities on an improved plan, with the view of gradually introducing improvements in the native methods. Efforts should at the same time be made to establish a better and less wasteful system of charcoal burning. The development and improvement of the native iron industry is as much within the scope of the legitimate duties of Government as the attempts made, by the establishment of model farms and otherwise, to improve native agriculture. The experimental operations here suggested must not be expected to yield revenue. If their cost is covered by the sale of the iron produced, that is all that can be hoped for. The object is not revenue, but to show the native iron-smelters the way towards improved and more economical methods, and to pave the way for the establishment of large iron works by private enterprise.

"These suggestions I submit with hesitation, as a late Resolution by the Government of India in the Department of Finance and Commerce, which was published in the *Gazette of India* of the 5th August last, lays it down that the establishment of iron works to be owned and worked by the State is open to grave objections, both economic and practical. That Resolution, however, primarily refers to the Bengal iron works, which are worked with coal, and where, therefore, a private firm or company can base its calculations upon certain data regarding the quantity and cost of the fuel available; and in the second place, it relates to the iron works proposed to be established in the Chanda District, where the greater part of the fuel will be furnished by the Warora coal-mines.

"In the Madras Presidency, the question is much more difficult. The absence of coal and the uncertainty regarding the annual yield of charcoal per acre in the areas which may be constituted reserved forests, make it impossible at present to furnish any safe data upon the ground of which private capital might be invited to embark in this industry on a large scale. This must wait until a sufficient extent of reserved forests have actually been established, and have by continued protection and steady improvement been converted into dense forest."

With regard to the effect on climate of forest protection, Mr. Brandis speaks very decidedly. He has no hope that forest conservancy can either materially alter the climate, or guard against the recurrence of excessive drought. No data, he says, "have been established which would justify the hope that by the creation of new forests or the improvement of those existing,

we shall be able to modify the limits of the regions of moisture, or otherwise materially to alter the climate of any district in the Peninsula. The great features of climate depend upon cosmic causes which are independent of local circumstances."

"It has been established by continued experiments made by L. Faurat in the forests of Halatte and Ermenonville in France that a gauge placed above the crowns of the trees in a forest, collects more rain than another placed in its vicinity at the same height from the ground but outside the forest. A brief abstract of these observations will be found recorded in paragraph 56 of my Report on Ajmere and Merwara, page 17. Observations of this kind will, it is hoped, some day be made in the Indian forests. Large extents of forest or large areas of irrigated land may have some effect in increasing the rainfall at certain seasons, and there is no doubt that in the vicinity of dense forests, and on irrigated lands, the air near the ground is generally moister during the dry season and the dew heavier. Nor is there any doubt that forests, if well stocked, afford effective shelter against scorching winds, and that in the hot weather the shade and shelter afforded by trees is a great boon, and is beneficial alike to crops, to man, and to cattle.

"These are, however, advantages which, though exceedingly important, only affect the immediate vicinity of the forest. The idea that forest conservancy can in any way materially alter the climate of the peninsula, or can guard against the recurrence of seasons of excessive drought must, I fear, be put aside, and our plans regarding forest administration in the peninsula must, at present at least, be framed without reference to such expectations."

With regard to the effects of forests in protecting the soil, and regulating surface and sub-soil drainage, the following remarks are made:—

"It is different in regard to the influence of forests in other respects. They protect the soil on slopes and hills, and there is good ground for believing that they regulate the distribution of the rain-water which falls upon the ground, and the surface and underground drainage. In this respect the action of forests is, we believe, most beneficial in a tropical climate. The action is this: *First*, the foliage breaks the force of the rain, which therefore falls upon the ground more gradually and gently; *second*, the loss by evaporation is less; *third*, decayed leaves, moss, twigs, and other matter on the ground in the forest act as a sponge, and prevent the rapid down-flow of the water; *fourth*, the soil which is permeated by the roots and is mixed with vegetable mould, is loose and facilitates the percolation of the water, which comes out at a lower elevation in the shape of springs.

"A further and most important result is, that less soil is washed away from the hill-sides and that less sand and silt are carried down by the rivers. Regarding this point, no doubt is possible. Wherever clearances are made on the hills in those districts of India which have a heavy rainfall, the loose soil is washed down into the streams and rivers, unless retained by terraces, lines of trees, shrubs, or other vegetation. There is not a district in the moister regions of India where the evil effects of denudation in this respect are not visible. The sand which is washed down from the denuded hills in the Hoshiarpore district of the Punjab, has destroyed the fertility of large areas. Ravines and torrents are numerous in the more thickly inhabited portions of the North-West Himalaya and in the Darjeeling district in Bengal. And yet in these districts the climate is so favourable, and vegetation so luxuriant, that hill-sides, which have been cut up by landslips and torrents, if left alone, often re-clothe themselves rapidly with grass, herbs, and other vegetation. Even on the Nilgiris the evil will be felt sooner or later, although these hills are favored beyond any hill range in India by gentle slopes, deep soil, and a moderate rainfall, which is distributed over nine months of the year, and most of which comes down in gentle showers. Every year masses of fine silt, which, if retained, might be a source of wealth to the planter, as well as to the Badaga, are washed down into the Bhayani and Moyar rivers, and unless the slopes are terraced, or coffee, tea, and cinchona are planted close in horizontal contour lines, the annual loss of rich loose soil will eventually make itself felt.

"The Ratnagiri district, in Bombay, is almost bare up to the crest of the ghats. Here the effects of denudation have shown themselves in this way :—There are four principal streams in the district, which, rising in the ghats mountains, run a short course to the sea, all of which were formerly navigable and important for the trade of the country. For small boats they are still navigable, but they are gradually silting up, because the hills on their head-waters have become denuded of forest.

"As regards evaporation, it may be useful to draw attention to the results of the experiment made at six stations in Bavaria, in the forest and in its immediate vicinity outside, which are recorded in the work by E. Ebermayer, entitled 'Die physikalischen Einwirkungen des Waldes auf Luft und Boden, 1873.' On page 159 the author states, as the result of these experiments, that the quantity evaporated in one year (1868-69) from a free surface of water, measuring one square foot (Paris), was as follows :—

In the open 3,180 cubic inches (Paris) } corresponding to a 598 millimeters deep.
In the forest 1,164 " " " " " stratum of water 319 " " "

"Ebermayer also states that the mean annual evaporation in the open, at different places, had been found to be as follows :—

| | Millimeters. | | Millimeters. |
|------------|--------------|------------|--------------|
| Vienna | ... 720 | Paris | ... 783 |
| Lausanne | ... 758 | London | ... 780 |
| Bar-le-Duc | ... 531 | Liverpool | ... 962 |
| Auxerre | ... 557 | Manchester | ... 780 |

"The great difference in the results, Ebermayer ascribes to the different construction of the instruments used, and to the different modes of placing them. In London it was found by Halley that, while in a room 208 millimeters evaporated during the year, the evaporation amounted to 1,848 millimeters if the surface of the water was freely exposed to sun and wind. In dry districts of India evaporation is naturally much more rapid than in northern Europe. Thus at Nagpore, the quantity evaporated from the Ambajhari tank during the dry season (8 months) was 7 feet, equal to 135 millimeters; and Mr. Culcheth came to a similar result in regard to evaporation from tanks in Ajmere and Merwara. It may be assumed that in India the effect of forest in diminishing evaporation is much greater than in northern Europe.

"The effect of forest upon the moisture in the soil is however of a most complicated nature. For while on the one hand the evaporation of the rain water is diminished, there is on the other no doubt that, under certain circumstances, trees and forests tend to dry up the soil, the roots drawing up moisture often from great depths, which is evaporated by the leaves. It is a common practice in Europe, to dry up swamps and wet places by planting fast-growing trees. Mr. D. E. Hutchins, Deputy Conservator of Forests, Mysore, informs me that the effect of plantations of casuarina and other trees, so successfully made at Bangalore and elsewhere on the Mysore plateau, has been, in some cases, to diminish the water-supply in wells in these plantations and in the station of Bangalore. His views on this subject will be found set forth in a paper regarding the influence of forests on moisture, appended to this report. (Appendix VI.)

"It will now be well to examine the probable effect of forests upon the water-supply in tanks, streams, springs, and wells.

"Speaking broadly, the result as regards the supply of springs, streams and rivers is believed to be this, that springs are better supplied and that streams and rivers are less subject to sudden floods, and have a more even and longer continued flow of water if their catchment area is stocked with forest than if it is bare. The effect is the same upon tanks which are fed from springs and streams. But upon tanks with a small catchment area, which are fed only by the surface drainage coming direct from that area, the effect is different. Tanks of that description would store the largest proportion possible of the water coming from the catchment area if that area were smoothed and plastered over, and made impermeable to the rain which falls upon it. In such cases a hard-baked surface of the catchment area, without any vegetation, would be most effective."

EDITORIAL NOTES.

A RESOLUTION published in the *Calcutta Gazette* deals with the proposed establishment of a Veterinary School in Bengal. Reports of severe outbreaks of cattle-disease have, from time to time, for many years past, reached the Bengal Government, and the need of a trained agency for the treatment of cattle is greatly felt. The establishment of a school for the special object of imparting instruction in veterinary science, and the training of a class of natives for service among the people, has long been under consideration. His Honor the Lieutenant-Governor is now of opinion that, as the efforts made in past years to convey instruction to the people in these matters have been attended with no lasting success, the question of opening a Veterinary School in Calcutta should at once be definitely taken up by the Government, and he has decided to refer it to a committee of gentlemen specially qualified to report upon the scheme. Of this committee, Surgeon-Major K. Melrod, M.D., has been appointed president, and, inspecting Veterinary Surgeon J. H. R. Hallen and Dr. T. Greenhill, members. This committee will report on the cost of such an institution, the staff to be employed, the best site for the school, and the instruction to be given. The report is called for before the end of the present cold season.

IN Messrs. Stenning, Inskipp and Co's Indian tea market review for 1882, the following advice is given to Indian tea-planters :—

Last year at this time we warned producers against coarse plucking and the results which would follow : we venture to point out that our anticipation of low prices is unhappily confirmed, for notwithstanding the good enquiry that has existed all the season for teas for price, values for common and medium are now positively at the lowest point ever touched, and good medium to fine are selling several pence below their intrinsic value. In 1881 fine picking was carried too far, and this season coarse plucking has been too much in vogue. It seems to us that the only safe plan is to pick moderately fine throughout, and without sorting too fine generally, to make moderate proportion of fine pekoe and broken pekoe, more particularly the latter, to sell here at, say, from 1/10 to 2/4 ; this would prevent a superabundance of medium kinds, and the depreciation in value which naturally follows.

Bulking.—The progress of this in India is slow, owing probably to difficulties attendant on want of room at the factory, and also to the danger of climate, but on several estates these difficulties appear to have been surmounted, and the teas turn out very satisfactorily ; it is evident that the condition of the tea should be better by not having to be turned out of the chest here, and exposed on the warehouse floor to the atmosphere, and afterwards trodden back into the packages : such treatment is a risk to the appearance of the leaf and to the flavour of the tea. Besides these disadvantages, the packages themselves with their lead linings are in a better condition than when they have to be opened and afterwards closed up : and there is also less delay in bringing to auction and in delivering to buyers. If tares run evenly in a break of Indian bulked teas, or are within 5lbs. of each other, a certain proportion, viz., one-sixth to one-tenth, is turned out to obtain an average tare. The advantages of bulking in India where it can be properly done, are very manifest.

The following letter from Mr. W. R. Robertson, M.R.A.C., Agricultural Reporter to the Government of Madras, was recently sent to Government :—"With reference to G.O., No. 1238, of the 11th instant, I have the honor to enclose two samples of Nankin cotton produced on the Saldapet Farm, Sample No. 1—in the seed ; sample No. 2—clean lint. It will be observed that there are several shades of color in the unginned sample, and that these differences disappear to a considerable extent when the cotton is ginned, due to the thorough admixture of the fibre in the process of ginning ; and during the spinning and weaving processes, I think a still greater uniformity in color will be secured. The Nankin cotton has been grown in this presidency as a botanical

curiosity for fifty years or more. It was originally imported from China, where the fabrics made from this cotton are in great demand for their cheapness and great durability. At one time, large quantities of Nankin cloth were exported from China, but I understand that its export has now almost ceased. I do not think the crop is grown anywhere in the Presidency, except on a very small scale. I remember seeing its growing at the Coimbatore Jail Farm about ten years ago; but Mr. Grimes, who, I observe, has been addressed, will probably submit the results of his experience there. I am now putting an acre of land under the crop, and this should in four or five months give enough seed for 20 or 25 acres of land which will probably suffice for experimental trials."

Mr. H. R. Grimes, Superintendent, Central Jail, Coimbatore, also wrote on the same subject as follow:—

"In reply to the Order of Government, dated 11th November 1882, No. 1238, Revenue, I have the honor to report that I have grown Nankin cotton on the Jail grounds since the year 1868, in which year two seeds were given me by the Hon. J. D. Sim, which both germinated; and from those two seeds, I have been enabled to plant at different times about 12 acres of land. It is a hardy description of cotton, grows in any description of soil, is perennial, and gives more than one keeping a year. I regret now I have not kept an account of how many times a year I have picked one field, or what quantity of cotton I obtained at each picking. The plant in the field grows to a height of about eighteen inches, but in favourable localities I have had it grow into a large bush, quite four feet in height. I have the honor to submit for the inspection of Government some of this cotton in the pod, some hanks of thread spun by the convicts from it, and two samples of cloth made from it in the Jail.

"Owing to the recent order of Government putting a stop to miscellaneous jail manufacture, I have just rooted up the last field of this cotton, which was planted in 1879, as I thought there would be no further use in cultivating. I have, however, a small quantity of it in my own garden, from which I can obtain seed and can recommence its cultivation if necessary. I believe it is not cultivated by the ryots in this district, but I am told it is so in the Tinnevely District. The great drawback to it is its shortness in fibre. I should much like to obtain fresh seed from Chunar or elsewhere, to ascertain whether it is superior to what I have grown. Brigadier-General Clerk, who accompanied his Excellency the Commander-in-Chief in his recent visit to this Jail took twenty yards of this 'Nankin' cloth, with a view of trying its suitability for the summer clothing of troops."

A CORRESPONDENT, writing to the *Ceylon Observer*, says:—Of the several varieties of rubber, the Ceara seems most suited for the Kalutara district, chiefly owing to its rapid and easy growth and its adaptability to dry soil though the district is a wet one. Swamps, if deeply drained and raised and above flood level, seem to answer. Of course on any land submerged by annual floods the rubber trees sicken and many die. Of the other varieties, Para, Castilleja, Landolphia, &c., little can be said, as they are of very slow growth, and for this reason it is not advisable for those who look for quick returns to attempt the cultivation of them, even though the soil suitable for them can be found and selected. A period of 12 to 15 years is rather a long time to wait, for it is probable, at the comparative rate they grow, that this period must elapse before the trees can yield a return of any value. The Ceara grows very rapidly in twelve months, and then begins at an average height at ten feet to throw out branches. Trees of even eight months' growth have a few clusters of fruit. At the end of the 3rd year, they attain a height of 13 feet or more with numerous branches spreading out 10 or 12 feet. The trunk has a girth of about 20 inches, a foot above ground. In its second year it commences to bear profusely, so that the price for rubber seed will soon go down. The inner branches are rather numerous and spindly. They ought properly to be thinned out with the object of growing thicker and stout lower branches, that would also, besides the trunk, be fit to be tapped in a few years. Strong winds occasionally play havoc with the branches when the tree is top-heavy. The branches snap off easily, and as they lie on the ground begin in a few days to throw out healthy shoots of a foot in length and before there is a sign of a root, the seed falling from the bursting capsules germ under the trees easily. It has already been pronounced a big weed, the growth of which will have to be checked and regulated in the

vicinity of delicate products. The roots spread on and a little above the surface, throwing out carrot-shaped tubers. These are relished by the pigs, but two coolies, it seems, experimenting on them as edibles, were poisoned to death. The rubber thrives best where the soil is rich and penetrable with an alavanga to some depth. It is not therefore advisable to plant out a field of them above a 100 feet or so above the bottom or base of a hill, but along ravines, flats, and gentle slopes, &c.; in fact, wherever there is a fair depth of soil, it can be safely put out. These plants high up and near ridges have not their leaves of a healthy bluish-green tinge, but have rather pale and sickly leaves and seem small in growth. Once a year after the crop, the rubbers drop their leaves entirely and look very bare, but throw out a fresh flush in three weeks or so. In all probability a tree grown under favourable conditions will not be sufficiently developed and fit till its 4th or 5th year to be operated on. Though the sap can be drawn from a three-year-old tree, the yield cannot be much or of much value, while the lacerating process in drawing the sap will retard its growth and make it a poorer tree at a desirable age. If the milk or juice is dropped into water it coagulates, and the rubber is ready in a few moments. As neither cardamom nor cocoa growing amongst the rubber seems to suffer from the rootlets or fallen leaves, they might answer a double purpose, and be used as shade trees.

THE following is the order of the Madras Government on the Conservator's Report for 1881-82:—The report of the Conservator compares favourably with that of the previous year, and the Board's exhaustive review leaves but little for the Government to remark on. The receipts and charges of the year under report were Rs. 5,06,456 and Rs. 3,89,892, respectively, leaving a surplus of Rs. 1,16,564 as against a surplus of Rs. 1,34,710 in the year 1880-81, and an average surplus of Rs. 4,638 in the five years ending with 1879-80. This result is satisfactory. The Government observe that, while the removal of Rs. 1,83,577 worth of timber by the Department last year was effected at a cost of Rs. 43,100, the removal of timber valued at Rs. 1,35,972 in the year under report cost Rs. 57,014. Similarly, while the removal of sandalwood, valued at Rs. 35,719, cost Rs. 9,851 in 1881-82, it cost only Rs. 8,689 in 1880-81 to remove a larger quantity valued at Rs. 38,265. These and other variations of the same character are explained in part by the increase in stock at the end of the year, and the fact that the establishment and up-keep expenses do not vary in proportion to the increase or decrease in sales. The amount expended on timber operations during one single year gives no practically useful result. In his next annual report the Conservator should endeavour to give the quantity of timber brought to depôt for two or three years, and the amount expended thereon. The figures, as they stand, need re-arrangement or explanation. The investigation proposed by the Conservator in paragraph 80 of his report should be of a searching character. It is probable, as suggested, that the disparity evidenced by the statement of apportionment of fixed establishment charges between the results of the departmental and the license and voucher systems is greater than what really exists. The figures should be well scrutinised, and the results noted in the report for 1882-83. The Board's observations on the subject are approved.

Reserved Forests.—The Conservator submits a statement, compiled from detailed information, carefully collected for the Inspector-General, exhibiting the extent of the reserves hitherto officially recognized as such. The estimated area, excluding those tracts for the reservation of which no authoritative sanction can be traced, is given at 1,182 square miles. The areas for each district will, as the work of selection proceeds, and as the tracts are formally taken up under the Act, be subject to modification. In this connection Major Walker reports on the operations of Mr. Cherry, the officer entrusted with the duty of selecting reserves in the Salem district during the year under review. The result is that the Committee have agreed in selecting 35 reserves conveniently distributed and containing 306 square miles, which is accepted as satisfactory. The people concerned have been served with notices of the intended reservations and their claims are being recorded. These will hereafter

have to be investigated and disposed of in accordance with the procedure laid down in the Forest Act. With reference to paragraph 10, orders have been passed on the Ganjam reserves. As observed by the Board of Revenue, orders on the reserves mentioned in paragraphs 14 and 15 must await action under the Forest Act. Adverting to paragraph 19, the Conservator should, in communication with the Revenue authorities, take steps for extending the area of sandalwood reserves in the Coimbatore district. The receipts from fuel reserves were Rs. 23,504, or Rs. 5,245 in excess of those of last year:—

| | Acres. |
|---------------------------|----------|
| Total area reserved | 160,259 |
| Equal to fully stocked | 60,475 |
| | Rs. |
| Receipts... { in the year | 23,504 |
| { up to year | 76,883 |
| Charges... { in the year | 6,849 |
| { up to last year. | 1,64,947 |

The Conservator should report on what data the elaborate and detailed statement of fuel reserves is based, and how far Government are justified in accepting it as accurate. The Conservator will pay particular attention to the remarks made by the Board in paragraph 9 of their Proceedings. Paragraph 87 of the report will be referred to the Public Works Department for report as to the delay which has occurred in utilizing the allotment made for Forest Officer's quarters in Kurnool. The interesting details furnished by Mr. Ferguson in his report show that the mahogany and India-rubber trees are on the whole doing well. The Conservator will adopt the Board's suggestion in view to the identification of the insect which has attacked the mahogany trees. It is not stated in the report whether any further experiments have been made for testing the tanning properties of wattle-bark. The Conservator's *resumé* of the work, accomplished by the Department since its organization in 1856, has been perused with interest.

On given amounts of food, the sheep produces, for the same weight of dry food, nearly twice as much manure as the pig, while the ox produces even more than the sheep. This difference is supposed to be due to the less digestible character of the food supplied to the sheep and ox. The quantity of manure produced during the same time, and for the same body weight is, however, very similar with the three animals, the greater consumption of food by the pig counterbalancing its lower rate of manure production.

THE business of growing pine-apples in the Bananas is in some years very profitable, and in others the reverse. An acre of good land will carry 6,000 plants of the sugar-loaf variety or about 5,000 of the scarlet kind. The price of land runs from £4 to £5 an acre, and if a site can be obtained on the bay so that the fruit can be easily shipped, the business of growing yields excellent results. The total export for the season is from four to five million pine-apples. The average price paid is about 1s. 9d. per dozen for the first cutting (the first year's produce), 1s. 6d. for seconds, and 1s. 3d. for thirds. As a rule, the scarlets go to the United States, the sugar-loafs to England. The wages paid are about 2s. per day for men, 1s. for women, and 6d. for children. Of late, the business of putting up the fruit preserved in tins has been commenced, and it has already attained considerable proportions. In 1880 about 300,000 tins were exported, and in 1881, the number was increased to 387,000 tins. Bad weather for several years in succession interfered with the success of the crops, but since 1880 the seasons have been favourable.

THE possibility of raising rust-proof varieties of wheat has been discussed without any practical outcome for an indefinite length of time. The author of the idea is unknown, but attempts to carry it out will doubtless continue to be made *ad infinitum*. We notice that Mr. William Farrer, of Warren, New South Wales, seeing that rust has again appeared in the Darling Downs, has written to the *Queenslander*, urging that further attempts be made in the way indicated. He says:—"I notice that the rust has again made its appearance in the wheat crops of the Darling Downs, and that the cultivation of Indian

varieties of wheat has failed to secure the immunity from rust that was hoped from it. I trust that no one will be led by this failure to doubt that wheat-growing can yet be established as one of the grand industries of Queensland; but it will not be established until a variety of wheat has been secured that is suited to the condition of your climate. I beg to submit the following suggestions in regard to securing such a variety. I will first of all point out the probability that a strong analogy exists between the rust of the wheat and the American blight of the apple. Careful selection has been brought to bear on the apple, and has resulted in the securing of a large number of varieties that are either blight-proof or so little liable to the blight as to be exceedingly valuable. Until similar careful selection is brought to bear on the wheat, I believe that little headway will be made with wheat-growing in Queensland. A rust-resisting variety may be secured by a happy fluke, but I do not think you ought to rely on the chance of that. The process that ought to be gone through I believe to be substantially as follows:—1. Let farmers who have rusty crops this year go through them carefully, and see if they can discover any heads that are free from rust. Such heads should be carefully watched, and plucked when ripe, and sent to the National Association or to some private person who would interest himself in this matter. 2.—Some of these sound heads would, in all probability, produce grain with rust-resisting properties. I would suggest that the grain from these heads be mixed, and sown under conditions that would invite the occurrence of rust, and that the sound heads from the resulting crop be again selected and saved. If this process be repeated a sufficient number of times, I think it more than likely that a number of rust-proof varieties will be secured; but they will have been chosen for ability to resist rust alone. 3.—The next process will be the selection from the rust-proof varieties of sorts that are also valuable for their milling properties. I expect that at this stage much might be gained by artificially crossing the different rust-proof varieties." Mr. Farrer is hardly justified in assuming that a strong analogy exists between the two cases cited. Analysis of certain varieties of apple—blighting and non-blighting kinds—disclosed the fact that the latter contained lime in considerable proportion, whilst from the former lime was almost absent. Applications of lime to the roots and branches had long been a recognised cure for the blight, and thus the analysis explained the cause of the immunity of such varieties as Winter Majetin and Northern Spy from the attacks of aphids. In the case of wheats the rust is a fungus, and rust-proof wheats have hitherto been found only amongst varieties having very hard straw, with grain that is better adapted for making macaroni than flour. Experience, so far, has shown that when the composition of the grain is changed in the desired direction, the straw loses its rust-resisting power. We do not wish to discourage intending experimenters; indeed, we shall be rather helping them by pointing out the obstacles which appear to beset their path.

THE Paris correspondent of the *Madras Mail* says:—"Ammonia and nitrates play so important a rôle in vegetation and cultivated soils, that too much importance cannot be given to clearly indicate what is exactly known, and what is uncertain. The Pic du Midi in France is a meteorological station, 3,164 feet above the level of the sea. Messrs. Muntz and Aubin have analysed the ammonia contained in the air at that altitude, but found no perceptible difference as compared with that contained in the air at the level of the sea and in the low lands. Water collected at the same height from rain, snow, and 'fog' contained less ammonia than that contained in the vicinity of London and Paris. In other words, the strata of air nearest the ground are richer in ammonia, due to the drops of water sweeping through a longer extent of air. It is to Bousisingault reverts the honor of demonstrating the permanency of ammonia in fogs and dew. That permanency has not been proven in the case of rain-water. One fact admits of no question—that the quantity of ammonia in the air is variable. Schloesing emits the opinion that ocean is the great reservoir of ammonia. This is not wholly exact, as certain electric influences can produce ammonia in the atmosphere. Messrs. Muntz and Aubin did

not discover any nitrates in the air. Such do not, as a rule, there exist. Nitrates are only produced in the atmosphere, following electric discharges, hence, why nitrates are always present in meteoric rain-water. The formation and the decomposition of nitrates by opposite causes, have been demonstrated in the case of drained lands by Berral and Kuhlmann. A new explanatory fact has been made known, that one class of animalcules makes the nitrification, while another destroys the combination of the elements. The process of nitrification takes place, according to the experiments of Messrs. Deherain and Maquenne, only in soils rich in organic matter, and exempt from the action of oxygen. These conditions can only be fulfilled in the case of bog lands or flooded soils. One fact worthy of notice, the decomposition of the nitrates, or reduction to their original elements, is accompanied by the production of protoxyde of nitrogen, commonly known as laughing-gas, and employed as an anæsthetic by dentists in "painless" tooth extraction. But what is the cause of these changes? When a portion of rich soil was heated, or submitted to the fumes of chloro form, it lost its property of decomposing the nitrates; on the other hand, when fresh soil was mixed with that heated, &c., the decomposition set in, because the animalcules (vibrios) existing in the fresh earth, attacked the organic matter, set free carbonic acid and hydrogen. The matter, seizing the oxygen of the nitrates, disengaged the nitrogen under the form of protoxyde. And the animalcules were readily detected, and were identical with the vibrios found by Pasteur in his celebrated researches on fermentation and decomposition."

ACCORDING to the Board of Trade returns, the imports for December increased £2,133,871, while the exports for the same month decreased £2,010,000, as compared with the corresponding month last year. The imports for the whole year increased £15,228,332, and the exports increased £7,454,478 as compared with 1881.

The falling off of over two millions sterling in the value of the exports last month proves conclusively that the trade of the country has received a serious check. It is to be observed, however, that the falling off is partly due to a fall in prices. The decline in the quantity of goods exported is not as great as in their value. No doubt a fall in prices means that the profits on the trade are smaller, and in not a few cases, we fear, it means that the profits have disappeared altogether. But still a decrease owing to a fall in prices is not so discouraging as diminution in the quantity purchased. There is, however, a diminution in quantities also, and not in one article only, but in most of the great articles of our trade, and in the quantities taken by so many countries that it would encumber our space to enumerate them. The most serious falling off, however, continues to be that in the cotton piece-goods sent to the Far East. For example, the falling off in the value of cotton piece-goods during December, as compared with December, 1881, bought by India, China, and Japan amounts to £454,000, or nearly one-fifth of the total falling off in the value of the export. There is also a falling off in the quantity of iron and steel exported, due partly to the check given to railway building in many directions. And generally it would seem that the purchasing power of foreign countries is not as great as it was some time ago. There can be little doubt that our merchants have overdone their business, that they have glutted the foreign markets, and that some time will be required before the stock thus accumulated is bought up and activity returns to our trade. But there is no reason to believe that it is anything more than a temporary check which we are now witnessing.

THE Government of India, Revenue, and Agricultural Department have made enquiries regarding sugar imported from Mauritius into the Bombay Presidency, and its competition with Indian sugars, the result of which may be summarised as follows:—In separate communications addressed to the Government of Bombay, to the Chief Commissioner of the Central Provinces, and to the Bombay Chamber of Commerce, the Government of India enquired what classes of sugar are mainly imported from Mauritius, whether they compete with the Indian article or are put to special uses, and to what extent the cost of railway carriage prevents the sugar-producer

of Northern India from successfully competing with the importer by sea.

The replies of the Governments consulted, as also that of the Bombay Chamber of Commerce, have now been received, and are published for information. They show that the imports of sugar into the presidency fall broadly into two classes: (1) refined sugars, and (2) *gur*, a compound of sugar and molasses. The first class is almost exclusively supplied by Mauritius; the second, mainly by sea-board from Madras. Such *gur* as comes from Northern India competes less with the refined sugars of Mauritius than with the shipments of *gur* from Madras. The imports from Mauritius meet a distinct demand for crystallised sugars, which at present Indian manufacturers make very little attempt to supply, and therefore a reduction of railway freight, although it might enable the *gur* imported by rail to compete on more favourable terms with that coming from Madras, would not divert the trade in refined sugars from Mauritius to Northern India. Meanwhile the demand for *gur* throughout India fully equals, it is believed, the supply, and this is probably one of the causes which retards the development of sugar-refining in the Bombay Presidency and elsewhere. The area under sugarcane in the Bombay Presidency and in the Central Provinces is, however, increasing, and the time may, it is trusted, be confidently anticipated when the indigenous article will displace to a great extent the refined sugars of various qualities at present imported by sea from Mauritius and China.

C. B. Pritchard, Esq., Commissioner of Customs, Opium and Abkari, Bombay, states that when the price of sugar is quoted for various ports of the Bombay Presidency at rates ranging from Rs. 7 to Rs. 17 per cwt., some of the quotations must be for coarse undrained sugar (*gur*), others for refined sugar, and others again must be averages struck from the prices of refined and unrefined sugar. Rs. 7 is somewhat below the present average price of *gur* in the city of Bombay, while Rs. 17 fairly represents the price of refined sugar.

Gur was formerly sent in large quantities from Northern India to Bombay for Guzerat, but since the opening of the Rajpootana Railway it has been sent direct, and very little, if any, now comes to the city of Bombay. When it used to be brought by this route, its price in Bombay ranged from Rs. 6 to Rs. 10 per cwt. *Gur* is largely imported into the city of Bombay from the Madras Presidency, from coast ports in this presidency south of Bombay, and by land from Kolkapore. The present price of this *gur* may be quoted from Rs. 6-8 to Rs. 10 per cwt., but as will be seen from the following table the average declared value in the years 1879-82 was over Rs. 9 per cwt.

Import of Gur from Coast Ports, including Madras Presidency—

| YEAR. | | | Quantity. | Declared value. |
|---------|-----|-----|-----------|-----------------|
| | | | Cwt. | Rs. |
| 1879-80 | ... | ... | 187,238 | 17,55,021 |
| 1880-81 | ... | ... | 194,739 | 18,99,484 |
| 1881-82 | ... | ... | 185,848 | 17,43,946 |

The imports of Mauritius and China sugar in the same period were as follows:—

| | | 1879-80. | 1880-81. | 1881-82. |
|----------------------|-------|-----------|-------------|-----------|
| <i>Mauritius.</i> | | | | |
| Sugar, refined | Cwts. | 504,552 | 742,899 | 802,087 |
| | Rs. | 82,03,073 | 1,18,34,728 | 95,41,486 |
| | | 1,339 | 2,226 | 1,218 |
| " unrefined | Cwts. | 4,766 | 8,921 | 4,601 |
| | Rs. | | | |
| <i>China.</i> | | | | |
| Sugarcandy | Cwts. | 24,488 | 27,211 | 38,507 |
| | Rs. | 5,85,999 | 6,50,538 | 5,78,821 |
| | | 52,849 | 1,12,882 | 89,463 |
| Sugar, soft, refined | Cwts. | 8,74,990 | 18,75,432 | 14,73,318 |
| | Rs. | | | |

In addition to the above, there have been importations of refined sugar to the following extent:—

| | | 1879-80. | 1880-81. | 1881-82. |
|----------------------|-------|-----------|----------|----------|
| From Calcutta ... | Cwts. | 98,075 | 27,387 | 88,285 |
| | Rs. | 14,98,788 | 4,48,087 | 4,86,490 |
| From Coast Ports ... | Cwts. | 17,460 | 3,811 | 16,425 |
| | Rs. | 1,48,310 | 65,369 | 2,43,426 |

Of the imports from Mauritius, only a very small portion is *gur*. This is inferior in quality to Indian *gur*, its present selling price ranging from Rs. 3-2 to Rs. 3-12 per cwt. Four qualities of refined Mauritius sugar are recognized in the Bombay market. Prices during 1881-82 may be quoted at from Rs. 18-8 for the first to Rs. 14-4 for the fourth quality: at present the prices are from Rs. 16-12 to Rs. 13 per cwt.

The prices of China refined sugar (soft) in 1881-82 may be quoted at from Rs. 15 to Rs. 17-10 per cwt., present prices ranging from Rs. 14-8 to Rs. 17. The price of China sugar-candy was from Rs. 20 to Rs. 25 per cwt. in the year 1881-82; present prices ranging from Rs. 20 to Rs. 22 per cwt.

It is not practicable to separate the re-exports of Mauritius sugar from Bombay from the aggregate re-exports of sugar of all kinds. The total re-exports are stated below:—

Re-exports to Foreign Countries, chiefly Persia, Turkey in Asia, Arabia, Zanzibar, Mozambique, Ceylon, and Aden.

| | | 1879-80. | 1880-81. | 1881-12. |
|--------------------|-------|----------|-----------|-----------|
| Sugar, refined ... | Cwts. | 48,296 | 109,443 | 69,843 |
| | Rs. | 8,26,549 | 19,37,846 | 12,37,024 |
| ,, unrefined ... | Cwts. | 155 | ... | ... |
| | Rs. | 1,575 | ... | ... |

Re-exports to Coast Ports, chiefly to Kurrachee and the Cutch and Kattywar Ports.

| | | 1879-80. | 1880-81. | 1881-82. |
|--------------------|-------|-----------|-----------|-----------|
| Sugar, refined ... | Cwts. | 207,971 | 293,542 | 284,004 |
| | Rs. | 34,49,117 | 49,99,354 | 39,67,512 |
| ,, unrefined ... | Cwts. | 933 | 1,094 | 345 |
| | Rs. | 10,943 | 4,135 | 4,082 |

The Hindoos formerly had a prejudice against Mauritius refined sugar on account of the use of blood in the refining process, but this prejudice has been overcome or forgotten, and Mauritius sugar is now used by all sections of the community. Mauritius sugar cannot be said to be used for any special purpose to the exclusion of Indian sugar, but it is preferred for the purpose of making sweetmeats, being found, when boiled down, to be more free from foreign substances than Indian sugar.

The Acting Secretary to the Bombay Chamber of Commerce says: that sea-freights are of course liable to considerable fluctuation, but the average cost of carrying one bag of sugar, weighing 1 cwt. 2 qrs., from Mauritius to Bombay, may be taken at 10 annas, while from China to Bombay it may be taken at Rs. 1-9. The average fluctuations are, we believe, from 8 to 12 annas from Mauritius, and Rs. 1-6 to Rs. 1-12 from China, while in both cases I give you the medium rate. The present charges by railway for the same weight of bag from the several stations on the other side of India are, I understand, as follows:—

| By rail from— | Rs. | A. | P. |
|-------------------------|-----|----|------|
| Benares to Bombay ... | ... | 3 | 2 8 |
| Allahabad to Bombay ... | ... | 2 | 13 6 |
| Mirzapore ... | ... | 3 | 0 2 |
| Dahli ... | ... | 4 | 3 0 |
| Lucknow ... | ... | 3 | 6 2 |

The prices at present ruling in Bombay for the different sorts of sugar are as follows:—

| Bengal. | | | |
|----------------------------|--------|----------------|--------------|
| Cast | No. 1 | Ra. 24 | per 168 lbs. |
| " | " 2 | " 22-23 | " " |
| " | " 3 | " 20-21 | " " |
| " | " 4 | " 18-8 to 19-4 | " " |
| Domo | " | " 15-18 | " " |
| Khujooria | " | " 17-18 | " " |
| Cossipore refined crystals | Ra. 17 | " | " |

| Mauritius. | | | |
|--|--------------------|--------------|-----|
| Small white dry crystals, Nos. 1 to 3, | Ra. 16-12 to 15-12 | per 112 lbs. | |
| Large " | " " " 17 | to 15-8 | " " |
| Soft white | " " " 15 | to 13-8 | " " |

| China. | | | |
|--------|-----------------|-------------|--|
| No. 1 | Ra. 5-8 to 5-10 | per 28 lbs. | |
| " 2 | " 4-8 to 5 | " " | |

The Committee are informed that the chief advantage which the Mauritius sugars have over the Indian sugars is that they are much more highly crystallised, which makes them more suitable for native confectionery of all kinds. In preparing sweetmeats the sugar has to be washed, and in this process, in its present form, the Indian sugar wastes about 5 per cent more than the Mauritius. China sugar is not highly crystallised, but it is whiter and sweeter than the Indian sugar, and consequently commands a comparatively higher price.

The Committee are informed that the Cossipore Sugar Factory at Calcutta is the only factory on the Mauritius system whose produce is known in this market. It is of a highly crystallized character, but being manufactured from inferior dates and not from the usual canes, it is said to be deficient in sweetness or saccharine matter, consequently it does not command as good a price as the Mauritius sorts. The quantity, however, of this description of Cossipore sugar sent here is very insignificant.

We understand that the Government of Madras has decided to encourage the cultivation of divi-divi as widely as possible. There are immense tracts of land in the presidency in which it is believed that the trees would grow well, as they are very handy and very little care is required in their cultivation. An inspection was recently made of a divi-divi plantation at Perambore which promised to prove very successful. About seven acres had been planted with divi-divi, all produced from seed from two parent trees, which are about 25 years old. The produce of these two trees during the past year had amounted to 500lb of pod, which, when sold, realized Rs. 18-10 nett. The dried pods fetched in the London market prices varying from £13 to £19 per ton. The owner of the Perambore plantation had, it appears, received offers for the seed at the rate of Rs. 12 an ounce, and for seedlings he had been offered Rs. 6 per hundred. Besides being of great value as a tanning and dyeing material, the divi-divi is also utilised for the manufacture of ink, and some ink which had been made on the plantations was pronounced to be exceedingly good.

No regular trade appears to have been established yet for divi-divi in Madras, but the following statement, which gives the quantity and value of the pods exported during the past five years, proves it is to be a profitable product:—

| COUNTRIES TO WHICH EXPORTED. | 1877-78. | | 1878-79. | | 1879-80. | | 1880-81. | | 1881-82. | |
|------------------------------|-----------|--------|-----------|--------|-----------|--------|-----------|--------|-----------|--------|
| | Quantity. | Value. | Quantity. | Value. | Quantity. | Value. | Quantity. | Value. | Quantity. | Value. |
| United Kingdom | Cwt. | Ra. | Cwt. | Ra. | Cwt. | Ra. | Cwt. | Ra. | Cwt. | Ra. |
| Calcutta | 165 | 660 | 15 | 73 | 109 | 550 | 150 | 688 | 88 | 596 |
| | .. | .. | .. | .. | .. | .. | .. | .. | 45 | 295 |

It is very apparent, from the letter which we reproduce in our correspondence column, that the analysis of soil given in the report of the Cawnpore Farm Experiments is not only by itself of very little value for practical agricultural purposes, but on the showing of our correspondent, it is positively misleading. It seems to us a matter much to be

deplored that some such explanation as that now forthcoming did not accompany the report when it originally appeared. Chemical analysis of soil at the best does not accomplish what the bulk of fairly educated men give it credit for achieving. Even conducted under the most favourable conditions it would be rashness in the highest degree to claim for it more than a sort of average result, while it is very doubtful if the same experimenter taking fresh samples of earth from the same field and conducting his analyses under identical conditions would be able to arrive at absolutely identical conclusions. As our correspondent says, "Those who know most about agricultural chemistry put the least trust in the results of an analysis."

We would go further, and say, that an analysis of soil while it may confirm the results of field experiments, it would nevertheless be the height of folly to appeal to analysis as a confirmation of field experiments unless both had been conducted in such a way as to eliminate all the possible sources of error; and this implies an application of crucial tests under every conceivable condition, and combination of conditions, to which in our estimation the Cawnpore Farm field experiments can lay no claim. In our opinion the limitation of Mr. Fuller's generalization by our correspondent requires still further limitation.

PROFESSOR DYER of Kew, has sent to India specimens of three kinds of wood taken from tea-boxes which had been sent home from India, probably from Assam. He says:—

"The enclosed pieces of wood are fragments of India tea-chests. We are anxious if possible to know the names of the trees which furnished them. A curious question has arisen about them which may lead to a lawsuit. Wood No. 3 has produced the complete corrosion of the lead with which the chest was lined. The metal is in fact converted into a coating of carbonate of lead, which you will see as a white incrustation on the surface of the wood. The result of this has been that the tea became damp, and deteriorated during the voyage. Nor was this the whole of the mischief; the wood has a sour acid smell which it communicates to the tea. All the chests packed in this wood proved practically unsaleable in London. It is therefore important to find out what this objectionable wood is, and gibbet it as a thing to be avoided for the purpose in the future. If you can help us with any information about it, we shall be grateful to you."

Mr. J. S. Gamble, to whom the specimens were sent, says in a note to a contemporary, as far as a mere guess from resemblance and the descriptions in the "Manual of India Timbers" goes, the woods were—

- No. 1. *Erythrina indica* or *suberosa* (certainly).
- " 2. *Derris robusta* (probably).
- " 3. *Atangifera sylvatica* (probably).

Professor Dyer's description of the odour and appearance of No. 3 was quite correct, but in order to make sure and also to ascertain if the wood of the wild mango is usually one of these used for tea-boxes, I have sent the specimens to Mr. Mann for his opinion, and hope to communicate the result to the *Forests*.

It will be a most important matter to warn planters of the damage such woods are likely to cause to their tea, and it is therefore to be hoped that we may be able successfully to trace the tree which gives such an unpleasant wood. I have known "champ" wood in Darjeeling give a similar scent, but the specimen was not "champ," which besides is not used for tea-boxes. In Darjeeling the common tea-box woods are—

Terai.—1, Toon; 2, Lampatia; 3, Semal; 4, Goguldhup; 5, Kadam; 6, Mandania; 7, Mainakat; 8, Udai.

Hills.—1, Toon; 2, Kabashi (maple); 3, Mahua; 4, Gobria; 5, Chilanni; 6, Lepokaphal; 7, Parsing—

while the Chittagong toon and others not well known are used; and in Chota Nagpore I have seen salai employed. Perhaps some one will favor us with a list of Assam and Cachar tea-box woods and help to complete the list.

(*Casalpinia coriaria*) has been circulated to the Forest Department with the following queries:—

- (1) Whether the information contained in the note is correct.
- (2) Whether the Department can add any further information.
- (3) What part of India is believed to be the best for its cultivation.
- (4) What steps the Forest Department is disposed to recommend to extend the cultivation.

Divi-divi is the pod of a leguminous tree known in botany as *Casalpinia coriaria*, *Libidia coriaria*, or *Poinciana coriaria*. The pod itself is also called Dibi-dibi, Libi-libi, or Libi-davi. It is a native of South America and the West Indies, and is chiefly found in low marshy situations in New Granada, Mexico, Venezuela, North Brazil, and Jamaica.

2. Dr. Wallich introduced it into India about the year 1830, and it has now been thoroughly acclimatized in South India, which, in soil and climate, resembles its original home. As the plantation near the Government Harness Factory at Cawnpore proves, it can be, with a little care, successfully cultivated in the drier climate of Upper India. The hot winds in the summer and the frost in the cold weather are, however, very destructive to the young seedlings. The seeds therefore should, in the first instance, be sown in a nursery in May or June, before the commencement of the rains, and the seedlings should not be transplanted till they are at least three feet high, by which time, it is supposed, they will be sufficiently strong to endure all the variations of weather to which Northern India is subject. In planting out, the trees should be put down 6 feet apart, so that an acre of land will contain 1,210 trees. Irrigation will be necessary as long as the trees are not sufficiently grown up to dispense with it. The *ghara* system of irrigation can be advantageously employed. In South India the tree takes three years to arrive at maturity, but in a drier climate it will perhaps require a longer period. Indian botanists recommend the cultivation of Divi-divi as a profitable, as well as an ornamental, plant.

3. The tree is cultivated for its seed-pods, which contain a large quantity of a most powerful and a quickly-acting tanning material, rather too strong to become a substitute for oak or babul bark, but very valuable as a cleaning and brightening agent in the after-process of currying, when it takes the place of sumach or *Rhus coriaria*. Both in England and at the Cawnpore Government Factory it is used as a substitute for sumach, which is a dearer article.

4. The actual demand for Divi-divi pods is not known, England imports about 4,000 tons every year, in addition to about 12,000 tons of sumach. But as Divi-divi is gradually ousting the latter, its demand appears to be capable of great expansion. For the same reason France, which now annually imports more than five million kilogrammes of sumach, will probably become a large market for this article. It has been proved beyond doubt that the tree can be profitably cultivated in India, and the quality of a consignment sent two years from the Khandesh Farm (Bombay) was pronounced by experts in England to be very superior, and fetched a higher price, than that imported from the West Indies. One great advantage in its cultivation is, that the tree requires no care after it has once grown up, and the proceeds are net gain *minus* the trifling cost of picking the pods. The ground underneath could be used for raising fodder grass, and the falling leaves for fuel or manure, the three great wants of the Upper Provinces. An acre of Divi-divi is supposed to yield not less than one ton of marketable produce, valued in India about Rs. 100, in England Rs. 150. The following are the actual results of the trial consignment mentioned above:—

| | £ | s. | d. | £ | s. | d. |
|---|-----|----|----|---|----|----|
| Amount realised by sale of 14 cwt. 16 lb. | | | | | | |
| of Divi-divi in London, at £15 per ton. | 10 | 12 | 5 | | | |

The following note by Baboo T. N. Mookerjee of the Revenue and Agricultural Department, regarding the Divi-Divi

Rs. A. P.
Equivalent of £6 17s. 7d. in Indian money, at 1s. 7½d. 83 1 1

| Brought over Loss Indian Expenses. | | ... | 83 | 1 | 1 |
|--|-----|-----------|----|---|---|
| | | Ra. A. P. | | | |
| Railway charge form Khandesh to Bombay | ... | 13 10 0 | | | |
| Cart-hire in Bombay | ... | 2 8 0 | | | |
| Shipping Charges, bundar fees, bill of lading, &c. | ... | 3 15 0 | | | |
| Addressing on 15 bags containing the pods | ... | 9 6 0 | 29 | 7 | 0 |
| Net proceeds | ... | 53 10 1 | | | |

It is not, however, known how many trees or what area of land gave the above proceeds. But Mr. Stormont, the Superintendent of the Khandesh Farm, who sent the consignment, reckons upon Ra. 80 as the net proceeds from one ton of Divi-divi on one acre of land, after paying the heavy export expenses. These expenses, he states, can be reduced by sending the article loose in ships' hold, as a packing material for bulky goods, in which state the Atlantic shippers are glad to receive it at quite nominal rates.

Dr. King is not of opinion that the cultivation of Divi-divi will turn out a hopeful financial prospect in Lower Bengal, and has furnished the following note:—

"The Divi-divi has been in cultivation in Bengal for many years. But although the value of its pods as a tanning material is well known, the cultivation of the tree has never excited much interest in the province. Seeds and plants of it have been available for distribution from this garden for years past. But they are very little asked for. The reason for this is no doubt the slow growth of the tree in the soil of Lower Bengal. Trees of it in this garden, which are certainly not less than from 18 to 20 years are only from 10 to 18 feet high. They have, however, large spreading heads. For example, a tree 18 feet high has a leafy head measuring 55 feet in diameter. On this account a comparatively small number of mature trees could be carried on an acre of land. I observe that in paragraph 4 of the Memorandum by Baboo T. N. Mookerjee, forwarded by the Government of India, it is mentioned that fodder grass could be grown under the shade of Divi-divi trees. This would not be the case in Bengal, as the shade is so dense that absolutely nothing will grow under a mature tree."

On the whole, Dr. King is of opinion that in Lower Bengal the cultivation of Divi-divi is not a hopeful financial project. Regarding Behar and the drier parts of the province, he speaks less confidently; but is not inclined to think that even in these parts it would be advisable to press the cultivation on landholders or tenants as a source of revenue.

Mr. Bennett, the Director of Agriculture and Commerce, speaks more hopefully of its prospects in the North-Western Provinces. We extract the following from his Report:—

"Various attempts have been made in these provinces to cultivate the Divi-divi. Three sowings were made at the Saharunpore Gardens in April, May, and June, 1879. In all three trials, the seedlings after attaining a height of one inch or so, died down under circumstances which led the Superintendent to infer that the seed supplied was to blame. Another trial was made on the banks of the canal near Cawnpore. The experiment was initiated under the care of an officer, whose interest was enlisted in the matter, but a change of officers subsequently occurred, and the experiment was finally reported as a failure, accompanied by an expression of opinion, that of all civil officers, canal officers had the least leisure for looking after such matters. In neither of the above instances can the tree be said to have had a fair chance. At the Cawnpore Experimental Farm about 10 seedlings were reared three years ago. Of this number one or two, which were transplanted to very poor soil, perished. The remainder were transplanted to fairly good soil, and have all done well, but have so far shown no signs of fruiting.

"At the Harness Factory, Cawnpore, about 3,500 trees have been successfully raised, and more are now being planted.

"From information kindly supplied by Captain Stone, in charge of the Harness Factory, it appears that the proper time to sow the seed is either March or July. If sown in March, the seedlings should be transplanted in the following July; but, if sown in July, transplanting should take place in July of the

following year. The trees commence to fruit in from 3 to 4 years after transplantation, and yield about 5 lbs. per tree. They grow to a maximum height of 15 feet, and planted from 12 to 15 feet apart. As a general rule, in tree planting to allow full scope in growth, a distance between trees in a plantation should be maintained of one-and-a-half time their height. Assuming, that 15 feet intervals will suffice, we have 192 trees to the acre yielding 8½ cwt. of pods per annum, worth Ra. 42-8 to Ra. 100 per ton, from which sum again has to be deducted the cost of carriage to the coast.

"Allowing 10 feet intervals, the number of trees per acre will be 436, and the annual produce 19½ cwt., at Ra. 100 per ton, Ra. 97-8, but it has yet to be shown how far the lessening of the interval between each tree affects the estimated produce.

"The tree is admittedly delicate, requiring care, irrigation, and good soil. It seems doubtful from the figures given above whether good soil in these provinces, distant as they are from the coast, would not yield a larger profit if laid down in good fruit trees; but the evidence so far either for or against the maintenance of Divi-divi plantations is inconclusive, and with the approbation of his Honor, experiments and enquiries will be instituted by this Department, with a view to obtaining more exact information.

"A small supply of seed has been obtained from the Superintendent of the Harness Factory, and is now being planted out at Lucknow. Efforts will be made to obtain a good supply of West Indian seed for distribution by March next, and care will be taken to give the seed a trial under fair conditions."

Experiments regarding its growth are also in progress in British Burmah.

BARLEY CULTIVATION FOR INDIA.

INTRODUCTION.

THE barley plant has been under cultivation from the most ancient time, and has always been held in great esteem as supplying food to man and *animated nature* under the protection of man. We find it mentioned in very high terms in the Bible—*vide* Deut. viii, 7 and 8; Jer. 2, xi, 8. Notwithstanding all the recent discoveries made in the vegetable kingdom introducing plants possessing more valuable properties for food, barley still maintains its character; and is most conducive to the wants and comfort of the millions of poor people and live-stock of all kinds (including the very valuable breeds of Arab and Barbar horses, which are exclusively fed with barley corn), and in all parts of the world. Indeed, at the present time, in extensive cultivation, barley stands first of all plants of the natural order *gramineae*, wheat standing second, and rice third, in the list. Speaking about India, barley cultivation is far more extensive and general than any other cereal grain plant in this country. This might be said of barley in other parts of Asia, Africa, Europe, and America; the reason of this extensive cultivation, because of equally extensive consumption, will appear from the facts delineated further on.

CLASSIFICATION OF BARLEY.

Botanists, with due regard to botanical characteristics observed in the ear of barley plants, have classified and placed them under five types described above. Since it will be found useful and interesting to persons wishing the improvement of the indigenous varieties of barley of India, and the introduction of new varieties from other parts of the country and the world, I accordingly subjoin a list of the principal cultivated varieties, together with a description of such of them as may help towards an improvement in the barley cultivation in India.

I.—*Hordeum vulgare* (the four-rowed barley).

To this type belonging the following varieties :—

- | | | |
|---------------------------|--------------------|------------------|
| 1. Spring Barley. | 4. Pearl Barley. | 8. Naked Barley. |
| 2. Summer or Sand Barley. | 5. Black Barley. | 9. Wheat Barley. |
| 3. Winter Barley. | 6. Russian Barley. | |
| | 7. French Barley. | |

In this list pearl barley, a sub-variety of winter barley, is the most valuable. It is very hardy, a heavy cropper, the earliest in coming to maturity, and the grain containing the largest percentage of gluten of all barleys under cultivation: the stem and foliage are also very nutritious fodder for the live-stock.

Pearl barley therefore recommends itself as the best barley for food for man and animals. Pearl barley, however, is not suited for malting purposes as well as other barleys are; so much the better for India, India requiring food, and not beer, porter, wines, spirits, intoxicating drugs.

Summer barley has the advantage over other barleys in that it will grow on the poorest soil, can be malted, but is poor in yield; because it has been grown from generation to generation on soil deficient in food ingredients necessary for its growth.

The other barleys, under this heading, do not require any special notice. Our Indian barleys, as found in Upper India, belong to *H. vulgare*.

II.—*Hordeum distichon* (common two-rowed barley).

Varieties—

- | | | |
|----------------------|-----------------------|-----------------------------------|
| 1. English Barley. | 3. Long-eared Barley. | 9. Golden Barley. |
| 2. Chevalier Barley. | 6. Black Barley. | 10. Librarian or Halliday Barley. |
| 3. Annot Barley. | 7. Large Barley. | |
| 4. Dunlop Barley. | 8. Italian Barley. | |

All of these varieties are suited for food for man and animals; and excepting the Librarian or Halliday barley, are also well adapted for malting.

III.—*Hordeum hexastichon* (the six-rowed barley).

Varieties—

- | | | |
|----------------|-------------------|-------------------|
| 1. Red Barley. | 2. Scotch Barley. | 3. Square Barley. |
| | 4. Bear Barley. | |

These barleys are noted for their easy culture, freedom from rust diseases, and for strong and firm stems which enable them to stand erect and brave wind and rain. All of them can be malted.

IV.—*Hordeum deficiens* (the Red Sea two-rowed barley).

This barley is most extensively cultivated in Arabia, Egypt, Abyssinia, and other parts of Africa. The strength and swiftness of Arab and Barbar horses are derived from this barley with which they are fed. This and an allied species, *H. muralepis* (A. Br.) are rarely cultivated in any other part of the world, and might be introduced into India as valuable for feeding live-stock.

V.—*Hordeum desertion* (the Tartar two-rowed barley).

Varieties—

- | | | |
|-----------------------|-------------------|--------------------|
| 1. Sprat Barley. | 3. Fulham Barley. | 5. Rice Barley. |
| 2. Battledore Barley. | 4. Putney Barley. | 6. Turkish Barley. |
| | 7. Dinkel Barley. | |

No special notice seems necessary regarding these barleys. In properties they are similar to the varieties of *H. distichon*, slightly differing from them in botanical characteristics.

USES.

The two parts—(1) seed or grain, and (2) stem and leaves, are valuable.

(1) *Seed or grain*.—From time immemorial, in every part of the world, barley grain has served as food to man and animals. In India it forms the staple food of the agricultural population, and millions of the poor of India, the rich also consuming it. The natives of India have different methods of preparing and using this cereal grain. A few words regarding these may be interesting.

A.—BARLEY, MIXED OR UNMIXED, AS FLOUR.

In India barley is rarely used singly for flour, but in most cases it is mixed with pulses and wheat, and then milled into flour. This is done in order to improve the flavour and nutritive properties of barley, hence poor people blend barley grain with wheat and pulses; no poor people will eat barley alone without one or more admixtures described above. With this end in view Indian cultivators raise barley as a mixed crop, and in the bazaars barley is sold as a mixed grain. Rich people, however, do not like admixtures; for them, therefore, barley is raised singly, and sold as an unmixed grain. So that barley is to be found in two states in the Indian markets—mixed and unmixed. Those who are not agriculturists (if mixed barley grain be not found in the market) purchase, according to taste, one or more pulses and wheat, blend them in different proportions with barley, reduce the whole into flour, and convert the flour into bread. By doing this, superior relish and economy in the cost of living are effected, wheat alone being so very costly that poor people cannot afford to buy.

Believing that it will be interesting and useful to those wishing to make experiments for ascertaining the effects produced on human or animal body, I join the different kinds of blendings with barley corn practised in India:—

| | | |
|----------------|--|------------|
| 1st blending | { Wheat (<i>Triticum vulgare</i>) ... 25 | |
| (gojao H.) | { Barley (<i>Hordeum vulgare</i>) ... 75 | 100 parts. |
| 2nd blending | { Barley ... 50 | |
| (jac-chana H.) | { Gram (<i>Cicer aristatum</i>) ... 50 | 100 " |
| 3rd blending | { Barley ... 50 | |
| (jac-matra H.) | { Green Pea (<i>Lathyrus vulgare</i>) ... 50 | 100 " |
| 4th blending | { Barley ... 75 | |
| (jac-kerao H.) | { White Pea (<i>Pisum sativum</i>) ... 25 | 100 " |
| 5th blending | { Barley ... 50 | |
| (bijhra H.) | { Grain ... 25 | |
| | { Wheat ... 25 | 100 " |
| 6th blending | { Barley ... 50 | |
| (bijhra H.) | { Green Pea ... 25 | |
| | { Wheat ... 25 | 100 " |
| 7th blending | { Barley ... 50 | |
| (bijhra H.) | { White Pea ... 25 | |
| | { Wheat ... 25 | 100 " |
| 8th blending | { Wheat ... 25 | |
| (bijhra H.) | { Barley ... 25 | |
| | { Gram ... 25 | |
| | { Green Pea ... 25 | 100 " |

Of these blendings, the last one is very superior, having all the nutritive ingredients necessary for the nourishment of the body, and is that with which experiments should be commenced. In feeding live-stock I would recommend, on physiological grounds, the mixed grain, whichever of these blendings is desired to be experimented with, to be reduced to flour, and then administered. A two-fold object is gained by this procedure, viz., easy digestion, and economy in feeding, the cost of milling being covered by the less grain given, and the feeder is advantaged by the health and strength imparted to the animal on which experiment is made. I might as well note here that on experiments with cattle, I have failed to get broken grain thoroughly digested by the animal, having on examination found broken grain in the dung of the animal so fed; but succeeded very well with flour which was thoroughly digested. Uncrushed or whole grain is still more difficult to be digested by animals, because it taxes and weakens the digestive powers too much. Horses have been found to digest this kind of food better than cattle, the latter having been found to pass it off with the dung in the very state it was administered. Our object in feeding these and other animals should therefore be not to tax and break down the digestive powers of animals—a very great point to persons wishing improvement of live-stock, and economy in feeding. Barley is a cooling food, and therefore very appropriate food for man and animals in India all through the summer and rainy weather. It is on account of this valuable property of barley, that Arab and Barbar horses fed with barley corn can bear more fatigue in the hottest part of the world than the best Indian horses, because Indian horses are fed with the heating grain all through the year—the Indians not knowing or over-looking the scientific theory—heat exhausting and cold bracing—a theory holding good anywhere and everywhere.

B.—BARLEY AS SUTTOO.

Sattoo is a well-known article of diet in Upper India, extending in the east from Western Bengal to the Afghan Frontier; on the west down south to the Central Provinces. In Bengal Proper, *sattoo* is rarely eaten, nor have I found it in vogue in any other part of India. It is peculiarly a poor labouring man's midday meal, which he prefers at this time for two reasons—firstly, because at midday he is allowed only a couple of hours' leave for refreshment, which he finds insufficient for the tedious and time-absorbing work of cooking and cleaning of cooking utensils; and, secondly, because economy is effected by eating *sattoo* at midday, and cooked food in the evening, after freedom from a day's work. There are three kinds of *sattoo* made in Behar, North-West Provinces, Oudh, and the Punjab:—(1) of pure barley grain, (2) of barley and grain in equal proportion, and (3) wheat and barley grain in equal proportion.

These three kinds of *sattoo* are prepared as described below:—

The persons desirous of getting *sattoo* made takes his wife, mixed or unmixed, according to choice, to the *dharmadaya* when he requests to fry it for him, remunerating him with either a little grain or a few *gundas* of *cowries* (if the quantity to be fried be little), or even seers of grain or annas of pice (if the quantity to be fried be large). On receipt of the remuneration the *dharmadaya* (a class of Mahomedan and Hindoo people going by this name) proceeds to fry the grain thus:—adjoining his *dharmadaya* (a long oven) the *dharmadaya* has a wide-mouthed earthen vessel in which, according to its holding capacity, he, his son, or his

of the female members of his family called *bharbhooja*, puts a quantity of grain; then he or she puts a quantity of burning sand from one of the *hauryas*, generally 12 in number fixed on the *dhaw* (two rows of six *hauryas*), and by means of a large iron spoon mixes the sand with the grain, sieving the sand out through an iron sieve. This finished, the grain is examined to find whether it is sufficiently fried or not. If found sufficiently fried, the fried grain is kept aside, and the remaining unfried quantity is fried in the same way; but if the grain be found insufficiently fried it is again fried, as at first, with another admixture of burning sand from the *haurya* fixed to the oven. Generally one frying is sufficient, but when the sand is not powerfully heated two fryings become necessary. After the grain is fried it is taken to the home of the person, and the female members of his family, if any, proceed to separate the husk of the fried grain by means of a lever-mill (*dhenki*, H.) or by means of a wooden pestle and mortar (*moosal* and *okhat*, H.), fanned out by means of a *scoop*, H., and the clean grain milled in the same way as wheat or any other grain is reduced to flour. The flour thus obtained is called *suttoo* H. or *chuttoo* B. If, however, the person has no one at his lodgings to prepare *suttoo* for him he gets it prepared by either the *pinharin* (female miller), or he gets it done by the *bharbhooja*, for which additional labour he has to be remunerated in cash or in kind as for frying, but somewhat more. *Bharbhooja's* *suttoo* is not properly made. This professional man does not bestow the proper time and labour on the preparation unless exorbitantly paid, but allows a great deal of husk to remain, and the milling is also very coarse. On these accounts, Indian people, whenever and wherever possible, prefer getting *suttoo* made either at their own homes or by the *pinharin*, this woman being paid at the rate of wheat flour, at so much per every five seers called *panseers*.

Now, *suttoo* is eaten in two ways, i. e., with sugar, and with salt. *Suttoo* made of pure barley corn, or barley and wheat is eaten by poor people mixed with *goor* or *rab*, moistened with water, the rich people using *cheener*, *khand*, or *misree* (refined sugar) scented with rose or *Keora* water, dissolved more or less, according to taste, with water. The upper classes of Hindoos and Mahomedans, whether of Upper Provinces or of Bengal eat *suttoo* in this way; but the millions of poor people eat *suttoo* composed of barley and gram mixed with salt and water with the addition of green chillies. In addition to these uses, *suttoo* is largely consumed in feeding valuable horses and costly cart bullocks, for which purpose *suttoo* composed of barley and grain, is preferred.

These are the different uses to which barley grain is put in India. In Europe and America, however, other uses are found. Beer and porter are brewed from barley-corn, and the starch used in laundries, perfumery, and various other articles are made from barley.

STEMS AND LEAVES.

(2.) Valuable fodder for the live stock can also be used, where abundant and available, for thatching purposes and bedding of live-stock. The dung of animals fed on the straw and litter used in housing them are excellent manure.

J. B.

(To be continued.)

NOTICES OF BOOKS.

THE QUINA BARKS.

A BOOK* has recently been published in Berlin, by Professor Flückiger of Strasburg, on the subject of quina barks. It contains 78 pages and eight lithographed plates, and is divided into 18 sections, under the following heads:—Origin; most important cinchonas; Remijia; home of the cinchonas; culture of the cinchonas; gathering of the barks; appearance and anatomical structure of the cinchona barks; composition of the tissue; seat of the alkaloids; varieties of cinchona barks; so-called false quina barks; quina cuprea; commercial statistics; chemical constituents of the quina barks; quantitative analysis of the alkaloids; manufacture of quinine; history of the quina barks up to 1737; recent history of the quina barks; list of recent works on the cinchonas and quina barks. The following is a translation of the preface attached to the work:—"The most important vegetable medicines corresponding with the progress of development of mankind are or were in large measure of oriental and south-European origin. America at first contributed but few gifts, and that to which now in domestic economy such an extraordinarily pretentious importance attaches, tobacco is of no importance in medicine, although nicotiana first

found an entrance into Europe as a 'wound-wort.' A century later there arose from the American plant world in quina bark a medicine whose action has found ever increasing recognition even in the face of the severest criticism of the present age. The market of the world may, by means of the sums of money it puts into circulation, indicate this bark as a most important medicine, but its value to-day rests much more on the fact that it is of service to the industry as a raw material. Since the discovery of quinine, and the consequent immediate commencement of its manufacturing production, the pharmacognostic importance of quina bark has altered commensurately; the greater certainty in the quantitative analysis of the alkaloids also has had the effect of throwing into the background an external knowledge of the bark as such. The revolution is taking place slowly; until quite recently in the pharmacological literature, the heading 'Quina Barks' still flourished in its pristine exuberant luxuriance. The progress in the culture of the cinchonas necessitates now another consideration of Chinology (Chinology or Quinology), as, with scarcely correct emphasis, this section of pharmacognosy is called. Unfortunately, the materials are still to a great degree wanting to carry this out to a satisfactory conclusion. For a systematic view the botanical knowledge of the plant-group under consideration leaves much to be desired, not to speak of the anatomical investigation of the structure of their barks. Even on the most important question, the increase of the alkaloids in those plants, we are deficient in information. The sudden flooding of the market with the Quina cuprea, which does not belong to a cinchona, especially differing throughout in respect of its tissue from the quina barks in the narrower sense, has brought to light for the whole world the surprising fact that quinine and the allied bases are not confined to the genus cinchona. The new views which are forced upon us by these observations lie quite outside of the allied question, what plants within the circle of the cinchonaceae generally contain quina alkaloids. The answer can meanwhile be only a very imperfect one. A variety of interesting topics are connected with the quina barks, both traditions, which have been and remained dear to the pharmacologists and physicians, and also glances into the future which are equally worthy of more detailed consideration. I was desirous, in bringing forward these views to the light of the present, to clear away the not always refreshing material of past ages and to open the road to a better insight. The short track which I have been able to make in this direction shows, however, some advance and invites to further labor. The following pages are, with a view to a larger circle of readers, taken from my 'Pharmacognosy,' but are fuller in many points; the importance of the subject appeared to me to justify such a proceeding. In this I have been assisted in the most obliging manner by my friends, Dr. J. E. de Vrij, C. S. I., in Hague, and Dr. G. Kewer (Zimmer quinine manufactory in Frankfurt)." So far the preface. In the first section of his work, Prof. Flückiger describes in a general way the *casarillo* jupe or true cinchonas and the *casarillo* bobes or false cinchonas, the former of which are confined to the mountain slopes of South America, while the latter are found much more widely diffused. Weddell's and Kuntze's divisions of the cinchonas are described, and the writer says:—"It is a question whether it is a gain to exchange the 51 varieties and sub-varieties of Weddell for the 14 varieties and bastards of Kuntze. Granted, however, that Kuntze was rightly informed as to the origin of the forms met with by him in British India and Java, it cannot be conceived why the wild growing South American cinchonas should correspond completely and entirely with those called bastards by Kuntze. Observations on plantations have certainly proved that crossings between cinchonas so nearly allied to each other can very easily take place, but in nature it is scarcely possible to distinguish whether we have to do with such a mixed offspring or with a form of a determined variety, produced by influences in some other manner. The view of Baillon, that about 20 varieties of cinchona are to be recognized, though not further confirmed, may still be the most correct one." Section 2 of the book deals with the most valuable cinchonas, viz., *auccubifolia*, *calisaya*, *laucifolia*, and *officinalis*, the "robusta" of Trimen being mentioned under the first, and *C. Boliviana* and *C. Ledgeriana* being described under the second. The third section is devoted to *Remijia*, 11 varieties of which are mentioned on the authority of Triana, the *R. purdieana* and *R. pedunculata* being specially referred to, as furnishing the barks described as quina cuprea. In section 4, the home of the cinchona is defined and the conditions necessary for its growth are detailed. In the fifth section a summary is given of the history of the introduction of cinchona culture into India, Ceylon, Java, &c., and the diseases to which the plants are liable are mentioned. We translate the concluding portion of this section, referring to the so-called cuprea;—"The alkaloid yielding barks which, under the name of Quina cuprea, have of late attained to such surpassing importance, belong to the genus *Remijia*, which grows under entirely different climatic conditions from most cinchonas. If the forestry departments will now possess themselves of the valuable *Remijia* the culture of fever bark trees can be extended into wide tracts of land from which they have hitherto been excluded. Contrary to what is the case in regard to the cinchonas, the *Remijias* are not confined to the hill regions, but suited to bear drought and higher temperatures, which prevail for example in the climate of the llanos in the region of the Orinoco and Amazon. Very likely among these or other allied trees may be found others similar with quinine-yielding barks, which would repay cultivation." In the next section Prof. Flückiger describes the methods of harvesting the cinchona bark in South America, and also the recently adopted processes of coppicing, mowing, and weeping. In section 7 the appearance and anatomical structure of the barks are described, section 8 dealing with the contents of the tissue and the seat of the alkaloids. In the next section the varieties of cinchona barks, *calisaya*, *laucifolia* and *auccubifolia*, as they are sent to the market, are described, "pale de

* Die Cinchoniden, in pharmacognostischer Hinsicht dargestellt von F. A. Flückiger, Mit VIII. lithographirten Tafeln. Berlin, 1883. (The Quina Barks, considered from a Pharmacognostic View, by F. A. Flückiger. With 8 lithographed plates.)

We have much to be thankful to the "China" of the German "Kina," which is a general term including the cinchona tree, bark, &c., and is applied by Prof. Flückiger, also to the "Cuprea" bark, which, as he says, does not belong to a cinchona.

gallinazo" being ridiculed as a fantastic name; "loxa" is also referred to. Section 10 treats of the so-called false quina barks, viz., *Cascarilla magnifolia* or *Quina nova*, rosa, &c., which contain no quina alkaloids and generally no alkaloids whatever. The 11th section is devoted entirely to *Quina cuprea*, to which Prof. Flückiger was the first to call attention in 1871, though Mr. Howard had so far back as 1837 received a piece of this bark and had noticed its quinine-yielding property. Its first appearance in quantity in the London market took place in 1879-80, and since then the imports have been very large. Prof. Flückiger describes the external differences between it and true cinchona bark, the shape of the bark cells being very distinct; the cuprea bark also yields caffeic acid, which is not the case with other quina barks. Another bark, introduced with the cuprea bark, but differing from it, is described as cinchonamine bark. In section 12 statistics are given of the imports of bark during the last few years into London and other places, and the prices for quinine which have ruled in Germany, together with the probable consumption of the sulphate in that country. Sections 13 and 14 deal at length with the chemical composition of the quina barks and the quantitative analysis of the alkaloids, several methods being given for the determination of the latter, but a footnote stating that a quick practical method is still wanting. In the next section the manufacture of quinine is described, and the efforts of Broughton and Wood are referred to. Section 15 contains a succinct history of the quina barks up to 1737, and section 16 carries the history up to recent times, and concludes as follows:—"The settling of so many still open questions in respect of the cinchonas must be hoped for from the forest culture of these trees, on the development of which the interesting official reports of the English and Dutch give continuous information. Very desirable is the complete systematic knowledge of the entire division of the cinchonas and the comparative examination of the barks of each separate variety from a chemical and an anatomical point of view." Section 18 gives a list of 38 of the latest works on the cinchonas and quina barks, Mr. Owen's manual being mentioned. An index adds to the usefulness of the work, which we hope will appear in an English form.

We may add that the value of Prof. Flückiger's work is enhanced by a series of well-executed engravings of various types of the true cinchona and of one of the plants which yield the cuprea bark. The first engraving represents the characters, in stalk leaf, flower and seed, of *cinchona succirubra* from an example supplied by the late Mr. McIvor in 1875. The second picture portrays *cinchona callisaya*, var. *lodgeriana*, "nach Exemplaren aus Java," the male and female forms of the blossom being carefully distinguished, and the peculiar small round dots on the lodgeriana leaf being prominently shown. In the case of this most valuable of all species there is a separate engraving, also from a Java specimen, displaying fully the character of the seed capsules, natural size and magnified, the enlarging under the microscope revealing pubescence on the capsule. Next comes a portrait of *cinchona langifolia*, also from a Java specimen, at once distinguishable from *lodgeriana*, by its much smaller leaves and its much more elongated blossoms and fruit capsules, the latter tapering more to a point than is the case with the short stumpy *lodgeriana* seeds. The specimen of *C. officinalis* figured represents a twig from Darjeeling and indicates characteristics of leaf, blossom and fruit, familiar to cinchona planters in Ceylon. Contrasted with this form are the long bean-like capsules of *cascarilla brevicarpa* (*magnifolia*) copied from Karsten's work on the Flora of Columbia. Finally, we have a figure of the principal type of the plants which, though resembling the true cinchonas in foliage, do not belong to them, but which yield a bark (cuprea) with much the same properties. The name of the plant figured in *Remijia pedunculata*, the cinchona *pedunculata* of Karsten's Flora of Columbia. The foliage is wonderfully like that of *C. officinalis*, but, after all is said and done, we do not believe cuprea bark is destined to supersede that of the true cinchona. The characters of the two barks under the microscope, as figured in this volume, show very marked difference. For purposes of comparison we have first a page devoted to figures showing cross sections through the young bark of *cinchona callisaya*, older bark of the same, and bark of *C. langifolia*. The outside bark, the cells, the pores and other vessels and constituents of the barks are shown in careful detail, and comparison proves the vast difference in the fibrous matter of the true cinchonas and that of cuprea bark. A large section of cuprea bark, given separately, shows in a still more striking light the structural difference of cuprea bark from that of genuine cinchona. To chemists, especially quinquologists and botanists, this work of Flückiger's will be of special value, while to the planter it is interesting as well as useful from the large amount of information it summarizes, and the well executed plates it contains of the leading species of the "Quina" plants, the cultivation of which in the Eastern World during the past quarter of a century has advanced so rapidly that there can be little hesitation in asserting there are now more cinchonas in Java, India, and Ceylon than could be counted in all the forests of the Andes.—*Ceylon Observer*.

SUBURBAN VILLAS.

Suburban Villas and Residential Farms in Kattywar, by Major H. L. Nutt, Bombay Political Department. Educational Society's Press, Byculla, Bombay, 1883.

MAJOR NUTT's little pamphlet is very carefully and neatly got up. The plans and estimates are accurate, full and easily understood. In advocating a system of Residential Farms, Major Nutt does not propose a sudden radical change in existing habits and customs. He hopes for a gradual and systematic improvement among agriculturists, by chiefs and other leaders of

society interesting themselves in his proposals for establishing suburban villas and residential farms. The following are the advantages claimed for residential farms:—

ADVANTAGES AND REMARKS.

Saving in time.—It is a fact that, in many instances, men and cattle have frequently to travel several miles to their fields in the morning, and the same distance back in the evening. In this way much time is squandered, and the coolest portions of the day are lost to agriculture.

Saving in labour.—It stands to reason that much vital force, otherwise available for the labours of the field, is expended on the mere journeyings to and fro.

Saving in wear and tear.—The agricultural implement would be kept on the farm, instead of being dragged backwards and forwards.

Preservation of health.—The general health of the cultivators, their families, and their cattle would be greatly improved by the free open air of the country. And, in like manner, the townspeople would be benefitted by the fact of flocks and herds being housed for the night outside instead of inside the town.

Preservation and local utilisation of manure—both solid and liquid.—This is a most important point, as will be acknowledged by all practical agriculturists.

Better protection of the crops.—The farmer and his family residing in the very midst of their fields, a view of which would be obtainable from their own house-door, it is clear that the crops would be better protected than if left to take care of themselves so much.

The necessity of fencing.—This would also greatly assist in the matter of protecting the crops.

Prevention of accidents.—The coming and going of herds being stopped, would reduce to a minimum the number of accidents which now and then occur in densely-populated towns.

Prevention of waste.—This is too obvious to require any special remark.

Estates would be consolidated.—It is a common custom at present for one man to cultivate distinct plots of land far distant from each other. A compact farm would obviate the waste resulting from such a custom.

Estates would be within reasonable control.—There is no disputing the fact that one of the most crying evils of the present day is that cultivators are allowed to take up more, much more, land than they can properly manage. The amount shown in the plan accompanying would be quite sufficient for a single cultivator with his family, and would conduce to a higher or improved description of farming.

The moral tone of the people would be raised.—The spirit of freedom would undoubtedly be encouraged, and the love of "hearth and home" fostered.

Major Nutt does not propose to take a resident in a certain town or village and suddenly transplant him, his family, and agricultural possessions to some out-of-the-way "jungle" place. What I propose doing, he says, in the first instance is simply to invite any individuals so disposed to occupy and cultivate suitably sized farms or holdings in close proximity to their native town or village—within a stone's throw, so to speak, of their present place of residence—so that their connection with their friends, the money-lenders, the grain-dealers, the potters, the carpenters and others, would not be interrupted in the slightest degree, but continued as heretofore. In this way personal security would also be provided for, as the town or village police would at all times be within call. Another objection which is of the same nature as the above as regards the idea of this agricultural change being instituted at once, and in all places, was that the nature of the land tenure and payment of revenue would be necessarily altered, to the derangement of existing custom. Well, all that need be said on this point is, that whereas the experiment is only proposed in a very small way to begin with, no derangement to speak of, in existing tenures, need take place at all.

I would commence operations in the immediate neighbourhood of towns and big villages, granting sites with frontage on a public road.

The holdings should not be too large, say not exceed 20 or at most 25 acres, of good culturable land, with a substantial house for a cultivator and his family, and suitable out-buildings for his cattle, implements, and general husbandry stock, including a commodious room or barn for storing grain. The house should be situated in the centre of the property.

A good well should be sunk close to the house. And a stout fence, planted with trees, should surround the estate, which would be approached from the public road.

Plans and estimates are attached, from which it will be gathered at a glance how I would propose to lay out each farm.

AGRICULTURAL BANKS &c.

We have received from Mr. A. P. Webbe a pamphlet on Agricultural Banks and supplemental legislation for agricultural relief. Mr. Webbe's suggestions are comprised in the following summary:—

(1) Agricultural Banks to be officially initiated and worked—and subsequently transferred to private agency under due safeguards.

(2) Loans to be granted to the *proprietary*, only on the "Floating Cash Credit" system, which will harmonise with the practice of the village usurer, and therefore fit in sympathetically with the wishes and requirements of the agriculturist—with this radical difference, however, that a fixed or maximum sum of indebtedness only will be permitted the agriculturist.

(3) Only land and houses are to be mortgaged to the Bank. Sureties, one or more, with or without collateral security as the case may appear to demand.

(4) Amount of loan (or "Floating Cash Credit") to be determined by marketable value of property or actuarial value of rent or income from the same. Substantial sureties to augment the amount of loan.

(5) Interest not to exceed 9 per cent per annum, and to be graduated to the extent of the property mortgaged. So that small proprietors too might be accommodated with cheap loans.

(6) Amount of loan and interest thereon to be officially determined.

(7) Loans to be granted without formal mortgage, and without fees and other incidental expenses.

(8) Form of application for loans to be officially prescribed; detailing number and area of fields, character and extent of buildings, mortgage, lien, &c., on them, and their approximate valuation. These, to the extent officially tested and verified, to constitute the mortgage deed and the basis of the loan.

(9) The position of *first* mortgagee to be purchased, if practicable, and the amount so paid to constitute part of the "Floating Cash Credit" authorised.

(10) No *second* mortgagee to be permitted after the Bank has purchased the position of *first* mortgagee. Where the position of *first* mortgagee cannot be purchased, or where there should already be a *second* mortgagee, no loan to be authorised.

(11) Debts to be recovered officially for Banks and at their cost as if they were "arrears of land revenue."

(12) "Floating Cash Credits" to be granted similarly to the *tenantry*, on two or more proprietary or other good sureties; and similarly recoverable from the sureties, as if they were "arrears of land revenue."

The scheme of supplemental legislation includes such points as the follows:—

(1) State demand to be fixed for a term of 30 years, at 33½ per cent of proprietor's rental *exclusive* of cesses; instead of 55 per cent *inclusive* of cesses as now (See 3.)

(2) All tenant right, as now understood, to be abolished.

(3) Rent to be fixed by settlement officer at periodical revision of settlement.

(4) Rent subject only to following enhancements under authority:

(a) Enhancement 15 years after revision of Land Settlement, up to one-sixth of rent fixed at such land settlement; when value of produce has augmented through rise in market prices.

(b) Enhancement, when land has been improved by or made generally valuable at cost of proprietor.

(5) State not to share in such enhancement.

(6) Rents subsisting for 15 years or since last settlement to be now enhanced on the basis of (4) a; and those that have been since enhanced more or less, to remain unaltered till next settlement, unless proprietor has improved (4) b.

(7) Land brought under cultivation after revision of land settlement not to be subject to State demand or enhancement till ensuing settlement.

(8) But tenants on such land to hold at settlement rates for like class of land *plus* an additional charge if superior to such land in locality. Tenant and proprietor may come to agreement and record the same in the Revenue Courts—rent to hold good till next settlement, unless as (4) b.

(9) Crops to be held hypothecated to proprietor as now.

(10) Tenant to compensate proprietor for injury to land.

(11) Tenant to be evicted under court sanction *only* for non-payment of rent. But to be compensated for unexhausted improvements. When any.

(12) Succeeding tenant, when any, whatever the interval of non-cultivation, shall pay only the same rent as the tenant evicted; unless as per (4) a and b, (8) and (17) involving outlay by proprietor.

(13) Rent to be abated when land is deteriorated or area diminished through causes beyond tenant's control.

(14) Tenant can vacate without consent of proprietor.

(15) But 6 months' notice to be given proprietor, or 6 months' rent paid him without notice.

(16) Tenants to vacate at 12 months' notice when land is required by proprietor—or to be compensated with one year's rent.

Notice to be served through Revenue authorities in all cases.

(17) Evicted and vacating tenants (11) (14) and (16) to be compensated for unexhausted improvements.

(18) No sub-division of estates to plots below 15 acres to be permitted. Eldest surviving male or female relative or child to inherit.

(19) Consolidation of dismembered estates into plots of 15 acres each to be effected gradually as present holder die off. Eldest male or female relative inheriting.

(20) Portion of tenant's holdings not to fall below 15 acres. Eldest surviving male or female relative or child inheriting.

(21) Consolidation of tenant's holdings into areas of 15 acres each to be effected on demise of present holders. Eldest surviving male or female relative to inherit.

(22) Revenue Department to possess complete jurisdiction in all matters. Revenue Board to be final court of appeal. All proceedings in consolidation of estates and tenants' holdings, to involve no cost to the parties concerned. Nor in the resumption of estates by cultivating proprietors (See 16 and 17.)

Mr. Webb contends and illustrates by instances that all tenant-right which makes the tenant a fixture, tends to the practical displacement and ruin of the peasant proprietary and small land-holders whose numbers are annually increasing. It also tends to the exclusion of capital, and ultimately pauperises the tenants.

The subjects dealt with are carefully thought out and elaborated, and the pamphlet forms a very noteworthy addition to the literature of the problems dealt with.

THE CATALPA: A VALUABLE TREE.

SOME time ago, Sir John O'Shanassy called attention, in the Legislative Assembly, to a celebrated American timber tree called *Catalpa speciosa*. The Ministers of Lands and Agriculture moved in the matter, with a view to procuring information, and have received reports from Mr. Gullfoyle, the Director of the Botanic Gardens, and Mr. Ferguson, Inspector of State Forests. Mr. Gullfoyle reports on the 27th November 1882, that the tree is said by many horticulturists and botanists in America, where it is indigenous, to be one of the most valuable timber trees known. One writer, Mr. C. H. Miller, of Fairmount Park, Philadelphia, says:—"There is a fine grove of catalpa in the park, some of them very large, one measuring 13ft. in circumference." A Mr. Arthur Bryant, of Princeton, Illinois, is said to have in his grounds a catalpa of the *speciosa* variety raised, from seed in 1839, which measured in 1879 (stump high) 3ft. in diameter. Other of the trees in South-Eastern Missouri measured in 1866, 3ft. and 4ft. in diameter, and 50ft. to a limb. In Indiana the trees reached a diameter of 4½ft. From one tree a limb was cut off 45ft. from the stump, a section of which was 8ft. long and 12½in. in diameter at the small end. A Mr. Barney, of Ohio, reported that a catalpa gate-post had been taken up, after being 46 years in the ground, and was found as sound as on the day it was set, no signs of decay being visible. Catalpa timber used in a stockade in Indiana had been found perfectly sound after being nearly 100 years in the ground. Similar particulars are given as to other pieces of this timber which have remained sound after being in use about 100 years. One log, after lying across a stream nearly 100 years, was cut into perfectly sound boards. Professor John Collet states that the timber is universally accredited with wonderful power to resist decay and time, and that after diligent inquiry, he had found no one willing to say the timber was liable to rot. Another writer stated that no decayed catalpa logs were ever found in swamps. The tree thrives in France and Germany, and in protected positions in the South of England. It grows rapidly, and the wood is remarkably light, fine in texture, and capable of receiving a brilliant polish. The bark was said to be tonic, stimulant, and antiseptic. The tree can be readily raised from seeds, and cuttings, and in this climate the seeds should be sown in September or October, and the cuttings planted out of doors in March or April. The tree has been of rather slow growth in the Botanic Gardens, the largest specimen, although upwards of 18 years old, being only about 10ft. or 12ft. high. That tardy growth was doubtless due in a great measure to the poverty of the soil. The tree would not bear much exposure to strong winds, and delighted in a loose and tolerably good soil. The present stock of young plants in the gardens, numbering some 30 or 40, averaged from 1ft. to 2ft. in height, and were raised from seed supplied by Sir John O'Shanassy.

Subjoined is Mr. Ferguson's report:—

"STATE NURSERY, MAEDON, NOV. 27, 1882.

"Sir,—I have the honour to acknowledge the receipt of your letter of the 24th instant, re catalpa trees (*speciosa*.)

"I have the honour to report that I received from the late Secretary for Agriculture, in 1880, a package of seed of the above tree, and beg to inform the honourable the Minister of Lands that I have here about 1,500 plants that have been transplanted into nursery rows, most of which will be fit for planting out permanently in the forest during the coming autumn and winter.

"The *Catalpa speciosa* is a native of the Southern States of North America, where it grows to a moderate-sized tree, seldom being met with more than 60ft. in height, with a medium trunk. When in flower it is a grand sight and like its congener, *Catalpa bignonioides*, of our gardens, is much admired for its large foliage and beautiful flowers.

"The timber of *speciosa* is much sought after in America for piles and posts for fencing, and has been found to last for many years when subjected to damp and marshy places, where other kinds of timber have perished.

"Since its introduction to this colony, I find it to be a tree of rapid growth, well suited for a dry country, and I have no doubt when it becomes better known it will be extensively planted.

"About 250 trees were raised in the State nursery at Longerenong in the Wimmera district, and during last season I had them transplanted into nursery lines, and they are growing rapidly.

"The *Catalpa speciosa*, like the *Paulownia*, walnut, ash and other deciduous trees in this locality, are liable to get out up by spring frosts, and I intend next season to make a permanent plantation of the catalpa in some more suitable locality in the State forests.

"I have &c.,

"W. FERGUSON,

"Inspector of State Forests.

"To A. MORRIS, Esq., Secretary for Lands, Melbourne."

OFFICIAL PAPER.

BEE-KEEPING IN INDIA.

(Continued from Page 55, Vol. VIII.)

| THE COLOR, SIZE, &c., OF THE BEE. | | | | HABIT. | | YIELD OF A COMB. | | |
|---|---|---|--|---|--|---|--|---|
| Thani Names of Bees. | Color. | Size. | Whether they always remain in one locality, if so, how long. | 1. Do they migrate; if so, why or when. 2. And whereto. | Do they swarm, and when. | Average Size of Comb | Quantity of Honey to be obtained from each Comb. | What proportion of a Comb is occupied with Honey, Bee-breed, and Breeding locality. |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| 1. Kamban thain Yes or Mahan thain Yes. | Body black, stomach red. | About 1 inch in length. | They are said to remain in one locality for some four months (Chitray to the end of Adil), April to the end of July. | 1. Yes. 2. When flowers are scarce. 3. Where they go to not known. | In April (Chitray Masam). | About 1½ feet wide by 1½ feet deep by 6 inches thick. | At a guess 4 measures or 3 Madras seer. | 1. About 6 inches in depth by honey. 2. About 3 inches in depth by bee-breed. 3. About 9 inches in depth by the breeding locality. |
| 2. Sippan thain Yes. | Do. | About ½ inch in length. | Are said to remain always on the hills, and for two months at a time in one place and to form a comb, store honey, and breed wherever they migrate to. | 1. Yes. 2. When flowers are scarce. 3. When they have eaten all the honey, or if robbed they go a distance of a few miles. | Whenever they arrive at a new place after quit- ting the old. | About 6 inches wide by 6 inches deep by about 2 inches thick. | At a guess ½ of a measure or 3/16 Madras seer. | 1. About 2 inches in depth by honey. 2. About 1 inch in depth by bee-breed. 3. About 3 inches in depth by breeding locality. |
| 3. Karan Theeduvai or Puthu thain Yes. | Do. | The size of a do- mestic fly or about ½ inch. | Are said to remain year after year on the hills and remain for two months in one place if not disturbed. They form a fresh comb, store honey, and breed where- ever they go. | 1. Yes. 2. When flowers are scarce. 3. When they have eaten all the honey, or if robbed they go a distance of a few miles. | Do. | About 6 inches wide by 18 inches deep by about 3 inches thick. | At a guess 2 mea- sures or 1½ Madras seer. | 1. About 6 inches in depth by honey. 2. About 3 inches in depth by bee-breed. 3. About 9 inches in depth by breeding locality. |
| 4. Sentheduvai thain Yes. | Do. | The size of a do- mestic fly or about ½ inch. | Do. | 1. Yes. 2. When flowers are scarce. 3. When they have eaten all the honey, or if robbed they go a distance of a few miles. | Do. | About 6 inches wide by 18 inches deep by about 3 inches thick. | At a guess 2 mea- sures or 1½ Madras seer. | 1. About 6 inches in depth by honey. 2. About 3 inches in depth by bee-breed. 3. About 9 inches in depth by breeding locality. |
| 5. Kasevan thain Yes. | The body is black and the stomach of a light brown color. | About ½ inch in length. | Appear to remain in the same place year after year if not disturbed. | 1. No; only when their num- ber becomes excessive or are disturbed. | All the year round. | The combs apparently are suited to the size of the hollows, which are said to be deep and very narrow, generally about 2 inches wide by 6 inches deep by 3 inches thick. | At a guess ½ mea- sures or 3/32 Madras seer. | 1. About 2 inches in depth by honey. 2. About 2 inches in depth by bee-breed. 3. About 2 inches in depth by breeding locality. |

Tabular Information—(Continued).

| Tamil Names of Bees. | YIELD OF A COMB—(Continued). | | HABITAT. | | | MODE OF HARVESTING. | MISCELLANEOUS. | | |
|---|---|--|---|-----------------------------------|---|--|--|-------------------------------|--|
| | What proportion of a comb is Wax and what refuse. | From what Flowers is Honey mostly obtained. | High or Low Elevation. | On Rocks or Trees. | In Holes of Rocks, Walls, Banks or Trees. | | Which bees might be domesticated. | Is there a Head or Queen Bee. | Is the sting venomous or painful. |
| | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 |
| 1. Kamhan thain Yee or Malen thain Yee. | About one-third wax and two-thirds refuse. | From the flowers of all trees, shrubs and the "Corringee" shrub which is blossomed, which is only once in about seven years. | At all elevations, high or low. | Precipitous rocks and high trees. | .. | Always at night are driven away by smoke from a torch: very few are burnt. No covering is used by the collectors, but on their return to the plains they bathe themselves with the water in which bruised tamarind leaves have been boiled in the proportion of quarter measure of leaves to one of water, which is said to remove all swelling and pain caused by any stings. Smoking is not employed, but the leaves of the "Shirdi Shernai Chedi" or plant is made into powder which is blown on to them, and the small of the leaves is said to drive them away. No covering is used by the persons removing the comb. Are removed in the day time by simply blowing them away. No smoking or anything else is employed. They are said not to sting. | The Kamhan thain Yee would not succeed. | Not known. | Is painful and causes much swelling, which lasts about two or three days, and the pain for a day only. |
| 2. Sippan thain Yee. | Do. | All trees and shrubs. | Lowish, say, 1,000 feet above the sea. Not in forest. | Thick shrubs. | .. | Smoking is not employed, but the leaves of the "Shirdi Shernai Chedi" or plant is made into powder which is blown on to them, and the small of the leaves is said to drive them away. No covering is used by the persons removing the comb. | Sippan Yee. This would not succeed. | Do. | Is painful for about two hours and the swelling is not much, and lasts for about two hours only. |
| 3. Karun Thoduvai or Ponthu thain Yee. | Do. | Do. | Always in holes and cool places or high elevations. | .. | In moderate-sized holes in rocks and trees and snake-holes. | Are removed in the day time by simply blowing them away. No smoking or anything else is employed. They are said not to sting. | Karun Thoduvai Yee. This bee might possibly be domesticated. | Do. | .. |
| 4. Senthoduvai thain Yee. | Do. | Do. | In grass lands and open forest. | .. | Do. | Do. | Do. | Do. | .. |
| 5. Kosuvan thain Yee. | About four-fifths wax and one-fifth refuse. | Shrubs and small plants, generally along channels water-courses and rivers. | Low and in the plains. | .. | In small holes, in walls, banks or trees, and snake holes. | These combs are removed without the aid of any smoke or covering, as the bees do not sting but only cling around one. | Kosuvan Yee. | Do. | .. |

Tabular Information—(Continued).

MISCELLANEOUS—(Continued).

| Tamil Names of Bees. | How do the Bees extract the Honey, and convey it away to the Comb. | How is the honey extracted from the Comb. | In which month of the year is Honey formed, and which are the chief months. | Is Honey put through any process to preserve it for a length of time. | For what purpose is Honey used. | Is the Honey of any one species of Bees sweeter or more bitter than another. | What Color is the Honey. | How is the Wax separated from the Comb and purified. |
|---|--|--|--|--|--|--|---|---|
| | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 |
| 1. Kottan thain Yee or Malan thain Yee. | The honey is removed by the legs and conveyed away thus. | The primitive method is to squeeze it out with the hand. In the Tinnevely Division, however, a magnified lime-squeezer has been introduced by the Forest Department for separating the honey from the wax, to overcome the filthy practice of squeezing with the hand. Sometimes it is said to be squeezed through a cumblly twisted round and round tightly. | Between beginning of May and end of July. Honey chiefly formed in June and July. All the year round, but in June and July most honey is formed. | Some say it should be kept in new earthen pots as they absorb all watery matter. A little wax is left in the honey in the proportion of 1/4 a pollum to every measure of honey. Others say honey is preserved by boiling it until all scum or froth ceases to rise. This thickens the honey, which is said to prevent it from fermenting. | As food; medicinally; as a preservative for fruit and ginger; for anointing the gods in the temples. | This is regulated by the flowers from which the honey is obtained. | Newly formed honey is yellow, but after it has matured a little, it turns a darker color. | After the honey has all been squeezed out of the comb, the latter is thrown into a pot of water which is put over a fire until the water boils, after which it is allowed to simmer, during which time the contents are ladled out with a coconut spoon a portion at a time and placed in a strong cloth which is twisted round and round by two persons at both ends over another pot of cold water thus causing the wax to escape through the cloth and fall into the water below. This process separates the dross from the wax. After this the wax has to be boiled again to clarify it, and when in the boiling state it is in the primitive way, poured into a round hole dug in the ground which is plastered with mud. After some 3 or 4 hours, when the wax has had time to congeal and become hard, it is removed out of the hole, and the surface of the wax is scraped until dross has been removed. A quicker method of obtaining the wax and causing it to congeal is to sprinkle cold water into the pot containing the liquid wax; this makes it congeal in layers, which is removed with a coconut spoon, and the process of sprinkling repeated until the whole has congealed, which method occupies only a short time according to the quantity of wax in hand. |
| 2. Sippan thain Yee. | | | | | | | | |
| 3. Karu Thoduval or Poatha thain Yee. | | | Do. | | | | | |
| 4. Sathoduval thain Yee. | | | Do. | | | | | |
| 5. Kottan thain Yee. | | | All the year round. | | | | | |

Mr. H. Sewall, Collector of Trichinopoly, writes regarding the Pachalmalai Hills:—

Wild bees are found in this district, chiefly on the Pachalmalai Hills. There are three varieties of them, viz., the Kathandal, the Poral, and the Siru or mosquito bee.

The first (Kathandal) is the largest bee, being about an inch in length and half an inch in diameter. Its sting is very painful, and sometimes results in death. These bees build their nests in crevices of rocks. To collect the honey a man is let down in a basket or a ladder fastened to a rope. He kindles a fire underneath the hive, which either stifles or drives away the bees, and then collects the honey in gourds slung round his waist. The nests, which are sometimes as large as 2 x 2 x 1/2 yard, are said to contain from 4 to 12 Madras measures of honey each, a measure weighing 4 1/2 lb.

The second variety is about half an inch in length. It has a sting, but it is less painful than that of the first kind, and not at all dangerous. It builds its nests generally in hollow trunks of trees or on their boughs. The nests are comparatively small. They yield from 1 to 4 measures of honey each. There is no difficulty in collecting this honey. The bees can be driven away by holding a torch under the hive or by striking the comb with a stick.

The third and last kind is the mosquito bee. It is about twice the size of an ordinary mosquito, and is inoffensive. It builds on trees and in the eaves of houses. The nests are very small, and yield only from 1/16 to 1/8 measure each.

No reliable information is available as to the quantity of honey produced in the district. The Sub-Assistant Conservator of Forests gives it as 350 Madras measures a year for the whole of the Pachalmalai Hills, while the head Assistant Collector puts it down as 800 measures for his side of the Pachalmalais. I think 500 measures may fairly be taken as the annual yield. The hill people sell their honey at about 8 annas a measure, and it is re-sold in the bazaar at about a rupee a measure. It is chiefly used for medicinal purposes. It also serves as food on festive occasions, being mixed with fruits, &c.

There is no honey exported from this district. On the other hand, it is said to be brought here for sale from Madura and other districts.

The first or the Kathandal variety is not in my opinion capable of being domesticated. The second and third kinds, which are found not only on the hills but also in the plains might, I think, be domesticated. But I doubt whether the natives could be easily persuaded to take to bee-keeping as is done in European countries. The demand for honey in these parts is not great, and the juice of sugar-cane, which is abundant, supplies the place of honey as far as the sweetening of food is concerned. They have, moreover, a prejudice against bees, and they consider it unlucky to have them near their houses. Probably the prejudice arises from the natural dislike to being stung.

The following extract is from a letter from the Temporary Deputy Collector of North Arcot to the Collector:—

In both the talooks (Chittoor and Chandragiri) of my division bees are not domesticated, and honey is taken from wild bees only. There are four varieties of bees, viz.,—

- (1) Pedda Eaga (large bee, which is of black color).
- (2) Pulla Teneega (dun-colored bee).
- (3) Thorra Teneega (bee which hives in the hollows of trees.)
- (4) Masara Eaga (grey-colored bee).

The first or the Pedda Eaga hives on the tops of hills; the second (Pulla Teneega) on the boughs of trees; the third (Thorra Teneega) in the hollows of trees and in the clefts of rocks; and the fourth (Masara Eaga) in the hollow of trees, in walls, and in the clefts of rocks; bees make their hives during May, June and July. Honey is extracted from the hives of the bees of the second, third, and fourth descriptions by the process of smoking. The hives of the bee called Pedda Eaga, which are made on the tops of hills, are generally inaccessible, except to the skilled *Erylas* (hill people) who extract honey from them by means of ladders and smoke. A bamboo ladder is let down, fastened to a peg on the top of the hill, and by means of this ladder one of the *Erylas* gets to the hive and extracts the honey, while others, from below, drive the bees by means of smoke from a lighted bundle of thatching grass. The man covers himself with cumby to avoid the sting of the bees. No information is available as to what distinction there is between the bees here and in the cold climates.

With the exception of the Masara Eaga, the other classes of bees do not remain permanently in one place. The sting of the Pulla and Thorra Teneega is not villainous, while the Masara Eaga does not generally sting. In the case of the Pedda Eaga, unless about 10 or 20 of them collectively sting there is no danger.

The quantity of honey produced annually in the jungles of the Chittoor Talook is estimated at about 4 maunds, while that produced in the Chamala and Panapakam Forests of the Chandragiri Taluk is estimated at 10 maunds. Each hive does not produce more than 2 pollins of honey. The price of a maund of honey is between Rs. 2 and 2-8-0.

About 3 or 4 maunds of honey is annually exported from the Chandragiri Taluk to Nellore, Madras, and Kumbakonam, and the rest is locally consumed for medicinal purposes. When no honey is available here, it is sent for from Madras in small quantities. Honey is not usually consumed as an article of food.

Mr. Stuart, Acting Collector of North Arcot, also forwards a series of reports received from Divisional Officers and Tahsildars, which may be found useful. It is therefore appended:—

I. GENERAL NOTES DEPUTY COLLECTOR.

(A.) *Talooks of Ponn and Wandiwash and Arni Division.*—Only a small quantity of honey is produced in this division. It is sold in the local markets at 6 annas a viss. There is no exportation, the

local supply being barely sufficient for the demand. There is, however, no importation.

(B.) There is no domestication of bees in this division.

There are four kinds of bees in this division. Their stings are very dangerous, and the honey can only be obtained by the *Iralars*, a wild jungle tribe. Their method of doing this is to strike the comb with a stone or spear, whereupon the honey runs out into pots previously placed underneath.

(C.) Of the bees found here, three kinds are very wild, and any attempt to domesticate would only prove fruitless. The fourth kind, however, called from its small size the Mosquito bee, which builds its hive in ruined houses and the hollows of trees, might be domesticated with a little care. The quantity of honey in a hive of these bees is very small, and is sour to the taste, owing to the bees gathering it from the flowers of the margosa and mango trees. It is often given to children in the belief that it will make them able to talk at a much earlier age than usual.

II. THE TEMPORARY DEPUTY COLLECTOR.

(A.) *Talooks of Chittoor and Chandragiri and Tirupati Division.*—The Chittoor jungles produce about 4 maunds, and the forests of Chamala and Panapakam, in Chandragiri Talook, about 10 maunds of honey per year. The price varies between Rs. 2 and 2-8-0 per maund. About 4 maunds are annually exported from Chandragiri to Nellore, Madras, and Kumbakonam. The remainder is consumed locally for medicinal purposes, and occasionally as an article of food. Small quantities of honey are brought from Madras when the local supply is exhausted.

(B.) There are four varieties of bees in this division, but none of them are domesticated.

(1.) *Pedda Eaga.*—These bees build their hives on the tops of high rocky hills. The jungle tribes extract the honey from the combs in the following manner: A bamboo ladder is fastened to a peg on the top of the hill and let down the cliff on which the hive is built. One man descends this ladder and gathers the honey, while others below drive out the bees by smoking them. There is no danger from their sting unless 10 or 20 of them attack at the same time. These bees do not hive permanently in one place.

(2.) *Pulla Teneega*, a dun-colored bee, which hives on the boughs of trees in May, June, and July. The honey is obtained by the smoking process. Like the above, they do not remain permanently in any one place. Their sting is harmless.

(3.) *Thorra Teneega.*—These bees hive in the clefts of rocks and the hollows of trees in the months of May, June, and July, and the honey is extracted by the smoking process. They do hive continually in the same place. Their sting is harmless.

(4.) *Masara Eaga or Grey-colored Bee.*—They build their hives in the hollows of trees in the months of May, June, and July. The honey is extracted by the smoking process, and, as a rule, the bees do not sting. These, unlike the foregoing varieties, generally continue season after season to hive in the same place.

(C.) There are no bees in this division likely to prove valuable if domesticated.

III. THE DEPUTY TAHSILDAR OF PUNGANUR.

(A.) *Punganur Division.*—About 50 maunds of honey are obtained yearly from the jungles of Avulpully and Kilapatla in this zemindari. It is sold at Rs. 2 per maund, and the supply is sufficient only for local requirements.

(B.) There are five kinds of wild bees found in this division.

(1.) *Para Teneega.*—This species, which is the largest found, hives on high and inaccessible rocks. The yield of a hive, which consists on an average of four combs, varies from 2 to 4 Madras measures, the *Iralars* driving the bees from the hive by smoking them. Their sting is very painful, and has occasionally proved fatal.

(2.) *Thula Teneega or Pulla Teneega.*—This species build their combs in the hollow trunks of trees, crevices of rocks, ant-hills, and the walls of uninhabited houses, if flowers and water are sufficiently near. This bee is of a reddish black color. The yield of a hive varies from 1 to 4 Madras measures. The bees can be driven out and the honey taken by merely shaking the hive.

(3.) *Komma Teneega or 2 Junt's Teneega.*—These bees hive in bushes and on the branches of trees. It has a black head with a grey body and wings. Only one comb is built, and the yield, therefore, is only about a quarter of that of the *Thula Teneega*. What it lacks in quantity, however, is made up for by the superior quality of the honey, which is the sweetest, clearest, and thickest of all.

(4.) *Jitta Teneega.*—This is the next in size. It hives in bushes and on the branches of trees. The honey is good, but the yield is so small that it is not worth the trouble of collecting.

(5.) *Musara Teneega.*—This is the smallest in size and resembles a mosquito. It builds its hive in walls, under stoves, and in small holes in trees. The honey is very sour to the taste, and the yield is very small. The wax alone is collected.

IV. THE DEPUTY TAHSILDAR OF KANGUNDI.

(A.) Considerable quantities of honey and wax are obtained from the jungles near the villages of Kangundi, Noolagunta, Adiri, Boodnagar, and Chadamoor. The season when the bees are most active is during the south-west monsoon, from May to August. The best honey is that made from the flowers of the *Pachala*, *Yerracheskia*, and *Veppala* trees; that gathered from other wild flowers is much inferior in flavour. The yield of the whole division is now only about 50 maunds. Prior to the present reckless felling of his forests by the zemindar, the yield was about 100 maunds. If this system of felling continues, it is to be feared that honey will cease to be produced at all in this division. The local price is from Rs. 1-8-0 to Rs. 2 per maund; but in Madras and Bangalore, to which places a considerable quantity is annually exported, about double that price can be obtained. Much of this

exported honey, however, consists really of honey and jaggery. The honey is separated from the wax either by simply squeezing the mixture in a cloth or by mixing it with water. The honey is then boiled to prevent its going bad.

(B.) There are four kinds of bees found in this division.

(1.) *Konda Tenege*, a black bee almost an inch long. They build their hives in the crevices of rocks. The yield of honey from a comb varies from 2 to 4 full measures, and is of very good quality. The honey is collected from the hive by the ordinary smoking process. The sting of this species is very painful, and has been known to cause death.

(2.) *Tholuga Baga* or *Thorra Baga*, a bee of $\frac{1}{2}$ to $\frac{3}{4}$ an inch in length, and of a red and black color. These bees build their combs in the crevices in the trunks of trees. The yield varies from $\frac{1}{2}$ to 1 measure, and the honey is much superior to that of the last-mentioned species in sweetness and flavour, but is inferior in solidity and clearness. The mode of taking the honey is very simple: the bees are driven out by striking the hive with a light switch, and the comb can then be taken with safety.

(3.) *Komma Baga*. These build their combs on the branches of trees, and excel all others in the sweetness and fragrance of their honey. The yield varies from $\frac{1}{2}$ to 1 measure, and the honey is collected from the hive in the same way as that of the last-mentioned species.

(4.) *Konura Baga*.—These build their combs on the eaves of houses, and sometimes on small boughs. The honey is of a very inferior quality, and the yield is less than a quarter of a measure.

(C.) Bees are not domesticated in this division, and there appears no probability of their being so.

V. THE TAHILDAR OF VELLORE.

(A.) No information given.

(B.) There are seven kinds of bees found in this talook.

(1.) *Periya Theni*.—These build their hives on high rocky hills, and will attack trespassers very fiercely. The bees are smoked out and the honey then taken.

(2.) *Kurumbi Theni*.—These build their combs on the big branches of trees. The honey is obtained by the smoking process.

(3.) *Thaduga Theni*.—These hive in the hollows of trees; they will sting if provoked; and the honey is collected by the smoking process.

(4.) *Kombu Theni*.—Build their combs on small branches of trees.

(5.) *Kosa Theni*.—Hives on walls.

(6.) *Chittai Theni*.—Hives on bushes.

(7.) *Kappu Theni*.—Hives on maize crops.

(C.) Bees are not domesticated in this talook.

The above extracts exhibit the principal information that the Board have been able to obtain.

B. SEWELL,

Acting Sub-Secretary.

SELECTIONS.

INDIAN TEA.

(Continued from page 60, Vol. VIII.)

PICKING.

THE sap begins to rise in March, and by the middle of April the first flush or picking comes on, and every available man, woman, and child in the neighbouring villages is hunted up to reinforce the permanent coolies of the establishment. A man and a boy per acre are required for a garden in full yield, at Rs. 4, Rs. 3, or Rs. 3-8, a month respectively. On a garden of 600 acres there would, therefore, at times be the responsibility of 1,000 coolies on the head of one European, who has himself only to rely upon for good management and efficient work. The flushes continue in greater or less strength and vigour from April to the end of October. A long, succulent shoot runs up of four, five, or even six leaves, and from these three or four are taken as the case may be; the whole shoot, stem and leaves, is picked off by the fingers down to the leaf which is left to shelter the bud from which the new flush is to spring. At times the growth is so rapid that by the time the pluckers have been round the whole garden in the course of two or three weeks, and have, with their nimble little fingers of both hands at work at the same time, taken off all shoots that are then ready for plucking, new shoots have come to perfection. It is astonishing how few mistakes these pluckers make; they become such adepts at the work that it is very seldom that too few or too many ready leaves are picked from any particular shoot.

PREPARATION OF THE LEAF.

During a good flush some 5,000 lb a day of leaf will be plucked on the plantation, and when it is brought to the factory, if it is intended to make black tea from it, must all be spread out in thin layers to wither. The planter's ingenuity, after all his floors and tables are covered, is much exercised to contrive surface for this necessary process. High racks are constructed, and divided by thin slips of wood or wire, so as to form lofty stands for series of light bamboo trays, which contain the leaf. In this way the air circulates among the bright, fresh green leaves, and what was life to them whilst they were on the bushes now brings decay, and by the following morning the day's picking is changed to a dark green colour, and the original leaves have become withered, soft, and pliable.

The rolling process, which follows next, is in some gardens carried out by machinery, and thereby much labour is saved, though perhaps not altogether to the benefit of the leaf. We will, therefore, keep to the old plan. A hundredweight of the withered leaf is given out to every three men, and if the leaf be succulent it will take them four or five hours to roll this properly; the work is hard and exhausting, and very often the men begin as early as 3 A.M. to get it well over before the great heat of the day comes on. Each man takes as much at a time as he can grasp and conveniently cover with his hands, then with arms and hands he gives a sort of rotatory movement to the leaf, which he presses with the palms and heels of his hand, and deftly gathers together with his fingers, working the mass so as to break all the cells of the leaf and free the sap, and at the same time to give it that curled and twisted form peculiar to manufactured tea. When sufficiently manipulated the mass leaves the hand in the shape of a ball, and is placed to ferment in baskets, which will hold about 2 cwt. each, lined and covered with damp blankets.

The amount of fermentation given to the leaf is a matter of great importance, and requires in its regulation much judgment and experience; the process can be checked or encouraged at the will of the planter, whose object is to produce a leaf of a bright colour, like a new penny, which is also the colour the finished tea should have after infusion.

When the proper amount of fermentation has been obtained, the balls of leaf are taken out of the basket, broken up, and thrown into metal pans, to be cooked over a gentle fire. This at once checks and stops the fermenting of the leaf, and makes it softer and more pliable for the second rolling, which is generally necessary at this stage. The leaf is from this time called "tea," but it would seem that it is not yet quite a finished article; for even after panning, the colour of the newly-manufactured tea is liable to change, becoming, as it is thought, oxidized by the action of the air. It is the planter's business to see that one process of manufacture succeeds another as quickly as possible, and immediately spreads the new tea on bamboo mats, or sheets of sile, and places it in the hot sun, which quickly dries up into the tea all the remaining sap, fixes the twist, and adds a bloom like that on a dried raisin. To prevent the possibility of the tea becoming sour and any loss of aroma from exposure, it is, after a short exposure to the sun, taken to the long, narrow firing-rooms, which run along the side of the factory, and placed in wire-gauze trays, holding about 2 lb each of tea, over charcoal fires, which are contained in long narrow troughs of masonry, about two feet high. Supposing 100 lb of tea to be over the fire at one time in these 2 lb trays, it would require an hour and a-half to dry the tea sufficiently for packing, and as space is limited, the tea is usually fired to such an extent as will prevent its turning sour, and finished off afterwards.

SORTING FOR MARKET.

All that remains is to classify and sort the tea, and to pack it for market. A certain amount of classification has been going on during manufacture; and the larger and coarser tea can be separated from the mass by sifting it, but after that the tea has to be shaken out pound by pound on to bamboo trays, and sorted by the quick fingers of boys and girls, who, whilst they separate the various qualities of tea, pick out all useless and foreign matter. This is a long and tedious work, and, to the uninitiated, seems hopeless.

Each estate keeps its own sawyers, carpenters, and smiths, who cut the trees from the forest—which the planter should always be careful to include in his land purchases—saw the planks, and make the chests in which the tea is packed, and which, lined with sheet lead, are sent off to Calcutta or London. The season's tea is sent in as few consignments as possible, to secure uniformity of appearance and taste to the various "breaks."

Now comes the Indian tea-planter's great difficulty. He has laid out considerable capital in land, in planting, in cultivation, in manufacture. He has worked hard, honestly, and conscientiously to produce a genuine and pure article; and now he wishes to sell his production, which those best able to judge pronounce to be equal at least to the very best and purest teas grown in China; but the brokers tell him that these and inferior China teas have so long held the first place in the markets of England, and that the public have been so impressed with the notion that no other tea can bear comparison with them, that they have the greatest difficulty in procuring a fair trial for his tea. The Indian planter finds that the vast quantity of China tea which is annually imported into England, and the variety of quality and flavour which these teas possess, together with the facility afforded for mixing growths of various districts and different qualities of teas, so as to meet the taste of the English consumer, have vitiated that taste and rendered the pure, unadulterated, unmixed, and wholesome tea of the hills of India, an unknown, and, consequently, unappreciated, article in the English markets. It very soon becomes plain to him that his interests are sacrificed to those of the retail dealer; and thus, when teas of widely different value, of flavour, of season, and of growth are imported in enormous quantities, the temptation to mix them, so as to force the consumption of low-priced tea at such a price as should of right only be commanded by those of the best flavour and growth amongst them, is almost irresistible by mercantile morality.

As most of the Indian teas are of remarkable strength and flavour, they are largely bought, not to sell in their pure state, but to mix with greatly inferior teas; and in order to keep an open market for these mixed and adulterated teas, the public, in many instances, is allowed to believe that Indian teas are quite fit drinking in their pure state; and the Indian planter finds that this interested and persistent misrepresentation stands in the way of every honest attempt on his part to introduce to public notice an article second to none of the very best produce of China. As he is unwilling that his tea should be regarded only as an article for giving body and

flavours to inferior China teas, and as he believes his tea to be worthy of the very highest place in the public estimation, and that the people of England can only rarely, as things are, taste the tea of the Kangra and other hill districts, he has now determined to be, as far as possible, the raiser of his own produce. He is encouraged to do this because though the taste for Indian tea is shown to be increasing by the fact that so many dealers comparatively now profess to sell it, an Anglo-Indian on his return home very seldom finds that, even in these shops, he can get the same kind of tea as he drank with so much relish in India. It is only in some unknown alip of a shop, or a room, where little attempt at publicity is made, that he can buy the real article he wants, out of the chest in which it was originally packed, in the garden in which it grew.

The planter believes that if he comes himself to England, and offers the public the produce of his own garden in its pure unaltered state, he will soon run John Chinaman's mixed and artificially strengthened rubbish out of the market, secure his own interests, advance the prosperity of India, and speedily command from the English public that support to which all honest trade is entitled. He will be at hand to afford any information possible regarding the cultivation, manufacture, and sale of his produce, and if it be true, that from any cause the present system works neither for the advantage of the producer nor the consumer, it is only right and reasonable that he should use every proper and legitimate means to improve matters without being considered guilty of any unseemly or unfair competition with wholesale or retail tradesmen. — *Gardner's Chronicle*.

THE SUGAR INDUSTRY IN THE FAR EAST.

ONE of the most interesting branches of commercial history to trace is that of the growth of the sugar trade, from its first rude beginnings away back among the mists of time, down to its present enormous development all over the world—a development which last year in the United Kingdom alone, with a population of 38,300,000 souls, reached 989,208 tons, of sugar,—giving an individual consumption of 62·77 lbs.; and of molasses 12,072 tons, or 80 lbs. per head.

According to Dr. Mosley, the great authority on the history of the sugar industry, the first notices we have of sugar are from the pen of Pliny and Dioscorides, the latter a sort of army surgeon, who accompanied the Roman legions in the first century of our era. What their description simply amounts to is that it was a sort of congealed honey found upon canes in India, of the consistency of salt, and, like it, brittle between the teeth. It was used at Rome as a medicine. Now, as the art of refining sugar and of making loaf-sugar was not known until the end of the fifteenth century, it has been very naturally conjectured that the sugar referred to as being in use at Rome, is no other than the sugar-candy of one's boyhood, the art of making which has been known in China from a remote antiquity. It is further known that large quantities of this article have for many centuries been exported to India, and that from thence, small quantities were sent to Rome. As, at least, showing the wide diffusion of the article, we may mention that so late as forty years ago the beautiful white crystals of Chinese sugar-candy were used for domestic purposes, to the almost total exclusion of every other kind of sugar, by the Europeans at the different settlements of the East. Canton was not only a great tea and silk port, but, in possessing this monopoly, was, as times went, a great sugar port, the annual export amounting to the respectable figure of 10,000 tons.

It will thus be seen that the successful introduction of the sugar-refining industry into the colony had, if we may so put it, somewhat like a historical warrant to authorise its introduction; and in saying this we do not in any way detract from the credit of those bold spirits who worked so hard and lost so much in placing it on a workable basis. As Hong-Kong, since its cession, has gradually absorbed whatever of the Canton trade that did not go to the treaty ports, it is natural to expect that it should also have a share in its sugar export, and with its greater facilities more than take up the position that Canton once held as one of the principal centres of distribution of refined sugar for the East. With sugar-producing countries all round us, sugar ought to become a staple industry here. From the statistics published by the Inspector-General of Customs at Shanghai, and from other sources of information, we learn that the cultivation of the sugar-cane, and the rough and ready refining of sugar, is more than ever seriously engaging the attention of Chinese farmers and capitalists on the mainland; this, indicating that in spite of all drawbacks there incident to such an industry, it possesses within itself all the elements of success. The native appliances for crushing the cane are of the rudest construction, and are propelled by animal labour, usually from four to five small oxen. The juice, after being collected in a receptacle in the ground, which holds from twenty to thirty gallons, is removed by hand to the boiling pans. These boiling pans are made of cast-iron and are manufactured at Fatsien, near Canton. The principal varieties of sugar made are the candy, the green, and the clayed sugars, of which the first and last are largely exported. In all the three descriptions, the process seems to be tedious, uncertain, and wasteful, involving a vast amount of human and animal labour. The endeavour to get rid of such hampering conditions, together with a desire to have freedom from official interference, in a large measure explains the erection of the refinery by a Chinese Company at Howington, East Point. The machinery for this concern, we believe, is supplied by a well-known Greenock firm. It possesses the latest improvements, and has cost 250,000 sterling. We learn that, with the exception of the manager, engineer, and one or two others, it is entirely a Chinese speculation, and altogether under their control.

The canes which at present are millitating so disastrously against sugar-refining in England and France, we imagine, will ultimately

conduce to the prosperity of sugar-refining abroad, especially in the East. Germany and Austria, in particular, it is well known, are bolstering up at the expense of their ratepayers and of other industries, the manufacture of beetroot sugar, by a system of bounties utterly subversive of all principles of free or fair trade. The only remedy for this state of things, as far as can be seen at present, is the reduction of all intermediate profits by the transfer of all processes connected with refining to sugar-producing localities. If this is the remedy, and facts tend to show that it is, the consequence will be the removal of English capital to the sources of production; and it must be conceded that nowhere is there such a combination of advantages as are to be found in China and the Philippines. In the first place there exist all suitable conditions of climate and of soil, labour is cheap and abundant, refining from the cane is speedily and less expensively effected than from beet, &c., and no other sacchariferous plant surpasses the cane, in the purity of its juice, in its extraordinary vitality and in the prodigality of its yield, and last but not least the constant, almost daily, communication with the principal sugar-consuming countries by lines of steamers proceeding to both hemispheres.

That we have an undoubted advantage in possessing abundance of cheap labour is borne out by the fact that the sugar-producing countries of Hawaii, Demerara, the Mauritius, Cuba, Natal (and North Queensland, if we mistake not) have, all in turn and at immense expense, imported field hands from these shores. Even the introduction of Chinese labourers does not solve the difficulty; for the Chinaman who has a genius for retail shopkeeping, the moment he has capital enough, turns his back on all field work, and sets himself up in a store in the neighbouring village or nearest town. Nay, more; further complications await the planter and the mill-owner from the coolies they have introduced. Referring to the introduction of Chinese labour into Hawaii, Mr. Thurmon of Honolulu remarks:—"The very large influx of Chinese during the early part of the year afforded no apparent relief to sugar and rice plantations in modifying the rates of wages, which have materially advanced since the workings of the treaty were entered upon, as they (the coolies) were found to be under sworn secret society obligations to maintain rates or figures found existing; and to secure sufficient to break such a monopoly would be to endanger our commercial relations and lose our autonomy." We may remark that, notwithstanding the troubles that afflict the Hawaiian sugar-planter, he has been doing very well. The sugar exported to the United States was calculated to be 45,250 tons—not a bad output for a group of mountainous islands of an area not much larger than Yorkshire.

From the troubles we have mentioned above, employers of labour in China and our neighbours in the Philippines are happily to a great extent exempt. The teeming millions of unskilled, badly-fed labourers render combination among this class next to an impossibility, and they are not adverse to emigration to the Philippines. Our local line of steamers render the expenses of specially chartering vessels for emigrants unnecessary; and the Spanish Government, if we know it at all, is not a Government to stand any nonsense from secret societies or trades-union obligations. When, in the present condition of sugar-growing and sugar-refining in the Philippines, we find that Manila sugar in the New York market competes to advantage with West India and Louisiana sugars and home sugar made from beet and other saccharine plants, it is a legitimate inference that with a still fuller development of the trade and with an ultimate reduction of expense consequent on the introduction of more economical methods of working, and as times goes on, we shall bid fair to command a wider and more profitable market. Let us take an instance. We quote from a number of the *Sugar Cane*:—"The steamer *Malabar* some time since arrived in New York with a cargo of 2,325 tons of sugar. This is said to have been the first steamer that has ever come from the Philippine Islands to the United States, and she brings what is believed to be the largest cargo of sugar imported to the United States. The cargo was consigned to Messrs. Willett & Hamlin of New York, who have sold it for \$360,000 to Messrs. Havemeyer and Elder, sugar refiners. The cargo will pay duty to the Government of about \$125,000." We do not know and have not cared to enquire whether this particular cargo proved a profitable speculation or not, but it does not take much acuteness to read between the lines, and to perceive that, if the sugar had been refined in Manila, what a great amount of charges for freight, for commissions of all kinds, and perhaps, for duties, would have been saved.

We refer in this article to no concern in particular, nor have we any interest or bias in favor of any particular inspection; what we simply wish to point out is that there is a great future for the sugar industry in China and the Philippines—speaking generally. One point must not be omitted; it is an unquestionable fact that the use of sugar among the Chinese is rapidly increasing; it is ceasing to be a luxury, and is fast becoming an article of diet. With such a market at our doors, capable of almost indefinite expansion, there should be no room for hesitation; especially as the experience of the trade shows that whenever sugar has been introduced into a district, the demand is maintained. As for the sugar-bounties, we can afford to laugh at them, for no beet refiner, be they ever so liberally subsidized, can continue long to compete with the exceptional combination of resources that Nature has placed at our disposal, in a teeming and industrious population, in a fertile soil, and in tropical sun. — *China Mail*.

NILGIRI BOTANICAL GARDENS.

THE report on the progress and condition of the Government Botanical Garden and Parks on the Nilgiris for the year 1881-82, which was submitted by Mr. A. Jamieson, the Superintendent, in July 1882, has been published, with the remarks of Government thereon. The latter includes the following:—"The

delay in the submission of this report, which was due on the 10th July, is noted with disapproval. In future the Collector should forward the Superintendent's report at once with any remarks he may have to make. An elaborate covering letter on a technical subject is wholly uncalled for." We read that "during the year under report, 377 fruit trees, 2,348 timber trees, 7,850 ornamental trees, shrubs and herbaceous plants, 2,317 packets of vegetable and flower seeds, 85 bouquets, and 141 baskets of out-flowers were sold by the gardens. The gross income from the sale of seeds, plants, &c., from the several gardens was Rs. 3,026-10-4, and the expenditure Rs. 16,426." The growth of potatoes during the year has not been satisfactory, but the Superintendent has obtained some new and approved kinds from England which promise to do very well. He again calls the attention of planters and owners of cattle on the hills to prickly comfrey and Bromo grass as fodder-producers. These fodder plants, he states, undoubtedly hold the first rank both as regards quantity and quality of their yield, and the ease with which they can be cultivated. A new fodder plant, tagasaste (*Oytisus profliferus*) has attracted Mr. Jamieson's attention, and he says that of all the plants with which he is acquainted, none seem to have taken more kindly to the soil and climate of the Nilgiris than this shrub. The plant would, he feels sure, be especially valuable in localities such as Kartary and Kalhatti, where grazing is year by year becoming scarcer. He has a quantity of seed and will be happy to give some to any one willing to give it a trial. Some interesting experiments with cinchona were tried. *Cinchona Carthagen* thrived very well, and the propagation of this valuable species has been so successful that a number of well-grown plants and cuttings were handed to the Overseer of the Dodabetta Plantation. And Sim's Park *Lodgeriana* did not succeed, owing to the soil being unfavourable. Here some foresight and a little thought might have prevented what proved a useless experiment. It is well known—or should be—what soil *Lodgeriana* will grow in, and surely the Superintendent knew what soil he had to deal with in Sim's Park? There is no lack of literature dealing with cinchona cultivation. Owen's Manual is one of the best works yet published, and besides that one there are King's Manual, Markham's "Peruvian Bark," Mr. J. Ferguson's essay, and others. What Mr. Jamieson prized most of the new plants introduced were the *Cavillona Elastica* plants obtained from Ceylon, and which he has no doubt will find a suitable home in Wynnad, where it will probably yield a profitable return to the cultivator. The black wattle appears to thrive very well in Ootacamund, and as the bark is valuable for tanning purposes, while the timber is of a superior quality, the Superintendent of the Botanical Gardens calls the attention of all who contemplate planting to this valuable tree. The cultivation of the wattle is simple and easy. Perhaps we may soon read what the Conservator of Forests says about wattle, as his opinion has been sought. Mr. Jamieson says of Liberian coffee:—

"This excellent coffee continues to grow luxuriantly and yields annually more abundant crops than the ordinary coffee growing alongside of it. The Native estate proprietors in and around Barliyar are now, I am glad to say, beginning to recognise its superiority over the Coffee Arabica and are now planting it pretty extensively on their estates. There can be no question that in a climate like that of Barliyar heavier and more regular crops may be calculated upon from this species of coffee. Nearly half of last year's crop was stripped from the branches before ripening by the high winds in November. However, sufficient was saved to raise nurseries and meet the demand for seeds."

Ipecacuanha has made fair progress, but has not increased in size and vigour, or made root growth sufficient to encourage a hope that it can ever be grown at Barliyar as an article of commerce. At his Excellency the Governor's request some plants are being tried in Ooty. Ceara Rubber trees have done very well, and there is a considerable demand for plants. The cultivation of Jalap has passed beyond the experimental stage, and it is now an established fact that Jalap can be grown successfully in Ootacamund, and will pay a fair return on the outlay, even at the price allowed by the Medical Stores. On the whole, the gardens have been useful to the presidency, but there seems to be something wanting; Rs. 13,000 per annum should produce better results. The experiments are generally on such a small scale that a slight accident may at any time destroy all the Superintendent has got of any new plant, and thus delay the publication of information which may be of vast importance to the agriculturists of the country. Professor Lawson's advent will probably give a stimulus to effort in this department, and we understand he will spend several weeks at the Peradeniya Gardens, Ceylon, before arriving here. There a much larger sum is expended on experiments, and the receipts for plants and seed sold are much higher.—*Madras Mail*.

CULTIVATION OF DIVI-DIVI.

Mn. W. R. ROBERTSON, Superintendent, Government Farms, reported to the Board of Revenue in October last that "Divi-Divi bush grown freely at Saidapet and its neighbourhood. We have in the Botanical grounds 17 bushes about four years old, raised from seed obtained from Bangalore which, last year, yielded 180 lb. of pods, and they are now bearing again. The seed will be collected and sown in view to the establishment of a small plantation." On the 20th October the Board of Revenue requested Mr. Robertson to make inquiries as to the demand for the seeds in the market for tanning purposes, and to report whether he thinks an extension of the cultivation would prove financially successful."

Surgeon-Major O. Bidle, M.B., Superintendent, Government Central Museum, reported to the Secretary to Government, Revenue Department, on the 10th November, as follows:—"With reference to G. O., No. 908 of 29th August 1882, I have the honor to state

that it appears to me that the Forest Department might institute small experimental plantings of the Divi-Divi where this could be done without incurring much extra expense. So far as my own observation goes, the tree does not grow very freely on the plains, and it is desirable to find out where it will thrive without much trouble, and where the attention necessary to get it to grow would render its cultivation too expensive. If its culture is likely to prove remunerative, the experiments of the Forest Department will be the best means of showing this to the people and inducing them to plant the trees. The Divi-Divi according to my observation thrives best at an elevation of from 2,000 to 3,000 feet above the sea level and likes a fair amount of moisture. The trees at Hoonsoor are the largest and most luxuriant which have come under my notice, and those at Guntoor indifferent." Major J. Campbell Walker, Conservator of Forests, reported on the 18th December as follows:—"I have the honor to submit the following information regarding the Divi-Divi (*Cassipouia coriaria*) called for in G. O., No. 908, dated 29th August last. On receipt of the order in question a circular memorandum was issued to Divisional Officers requesting them to report on the cultivation of the tree and the prospects of successfully extending it. Replies have reached me from all districts except Nilgiri and Godavari. The tree is not cultivated in the Kurnool, Trichinopoly, Coimbatore, North Arcot, Palghat, Nilambur, Bellary, Tinnevely, Cuddapah, and Madura Divisions. The Assistant Collector, in temporary charge of South Canara Forests, reports that he knows of no cultivation in the district, but the Collector adds a note to the effect that he has seen some plants of merely two years' growth which look as if both soil and climate suited them, and that he has three promising young trees of his own. The Head Assistant Collector in charge of Palghat thinks that the tree might thrive in the Waiyalar Reserve, but fears the moisture would be too much for it elsewhere in his division. The Deputy Conservator of Wynnad Forests refers to a few trees grown in a coffee plantation of Colonel Woolridge, a resident of many years' standing; but gives no information as to their condition or the soil, aspect, and elevation where they are growing. He is anxious, however, to receive seed for experiment. The Deputy Conservator, South Arcot Forests, reports that experiments are being tried by Mr. Weld, Sub-Collector, near Tindivanam, and states his opinion on observation of these and other plants growing a mile from the sea that the tree is likely to succeed in sandy soil at Cuddalore. He has failed in his own efforts to introduce the Divi-Divi into topes and reserves, and the yield from trees he has known elsewhere in the district is not satisfactory. He refers to some trees he recently saw in Wynnad, probably the same as those mentioned in paragraph 5, and describes the wood as white, hard, and useful, and the growth of the tree slow. The Deputy Conservator of Salem Forests states that the Divi-Divi is cultivated to a small extent in his district by private individuals, and, referring to a communication from the proprietor of the plantation near Madras, he advocated the opening of an experimental plantation by the Forest Department in the Salem District. He says a stiff clayey soil is generally well adapted to the tree, but wherever the *Acacia leucophylla* flourishes, it is safe to plant the Divi-Divi, and this is one of the best guides in selecting a site. The Sub-Assistant in charge of Goomsur and Surula Forests reports that he has now six trees in the experimental teak plantation at Moyagudda, which were procured from Chiacola in 1870, and are now thriving, averaging in height 13 feet with a girth of 2 feet at 1½ feet from the ground. He considers an experiment is likely to succeed. This information is too meagre to justify definite conclusions for or against extensive cultivation, but I agree with Dr. Bidle's suggestions, recorded with G. O. No. 3883, of 20th November last, and think we cannot do better than institute a number of experiments in different localities. I would suggest Mangalore, Nilambur, Waiyalar, Manantoddy, the Anaimalais, parts of Salem, Tinnevely, Madura, South Arcot and Ganjam as localities where suitable arrangements could be made for experiments, and if Government approve and obtain seed for the purpose, I will issue the necessary orders. The tree grows fairly well in Madras, and, I believe, in Bangalore, and useful information regarding it could probably be given by the Honorary Secretary to the Agri-Horticultural Society and Superintendent of the Lal Bagh Gardens."

Order of Government, dated 17th January 1883—"The Divi-Divi tree (*Cassipouia coriaria*) has long been cultivated to a small extent in this Presidency. It grows and bears abundant seed on the worst soils in Madras. It will probably succeed better at a higher elevation, and in view of the commercial value of its pods and the increase in their export in late years, the Government resolve to sanction the proposal of the Conservator of Forests to cultivate the tree on a large scale in the places named. The Board will call upon Mr. Robertson to expedite the submission of the report asked for in paragraph 2 of their Proceedings, dated 20th October last."

EKMAN'S PATENT PROCESS FOR TREATING WOOD AND FIBROUS PLANTS.

MESSRS. HINDE & CO., of Calcutt, who are agents for Mr. Ekman, have now been good enough to fulfil their promise of sending us specifications of patents and also estimates. It appears that the chemical agents used in the process of maceration are sulphuric acid and carbonate of magnesia in the proportion of two of the former to one of the latter, the solution giving approximately 1¼/10ths per cent of magnesia and 44-10ths of sulphuric acid. Magnesia is preferred to either potash or soda as being less injurious to the texture of the wood or fibres treated. The substance to be prepared is boiled in the solution under pressure; gas and steam being also blown off, mainly, it would seem, to prevent burning. Modifications of the appliances employed would

have to be made with reference to materials treated, such as bamboo, reed, &c., full information being afforded by the agents on reference to them. The royalty on the preparation of paper pulp is \$1 per ton of dry pulp produced; the charge for "filaments" and "ultimate fibre" (fitted for textile purposes), we suppose, being somewhat higher, and to be arranged through the agents. Paper works, such as Mr. Ekman's in London, cost \$10,000, the machinery alone coming to \$7,100, thus:—

| | |
|--|--------|
| Four jacketed boilers 12 feet long inside by four feet diameter, with lead lining, supports and fitting, cost, erected, say | £2,500 |
| Two small generating boilers, capable of supplying steam to the other boilers, up to 90lb pressure per square inch, say | £350 |
| Kiln, to burn 500 tons of carbonate of magnesia per annum, will cost about | £150 |
| Apparatus in laboratory (exclusive of building) to make chemicals for 1,000 tons of dry fibre or paper pulp per annum | £600 |
| Eighty-inch paper machine, speeded from 20 to 150 feet per minute, with stuff chests, knotters, back water pumps, intermediate rolls, cooling cylinder, two sets ordinary calendars, damping apparatus, steam engine and gear, would cost, erected | £4,000 |

We are told that working day and night such a machine would produce from 20 to 30 tons of paper per week, say 1,000 to 1,500 tons a year according to the sorts made. Working only by day, which would probably be best to begin with, it would easily make 600 tons a year. It is added that—

The other arrangements of the Mill should be made with a view to working eventually up to the full power of the paper machine.

Then follow long details of breakers, washers, potchers, beating engines, farms and clay-mixing tanks, alum and size, and two colour coppers, bleach-mixing tanks, &c., including a 200-horse power engine and corresponding boilers, bringing the total cost up to £19,795, still apart from buildings; and we are told that such a mill could be increased to turn out 50 tons of paper per week for an expenditure not exceeding £10,000 for machinery, &c.

Such a mill, if built at Calcutta, for the working up of jute with others at Bombay and the various capitals or centres of cotton districts for the preparation of waste cotton, would go a good way to supply the total present demands of India for paper. A turn-out of 50 tons per week would amount in a year to 2,600 tons, or 52,000 cwt., equivalent to 67,600,000lb. But we, in Ceylon, have only a general interest in such huge paper factories. What we want to know is how best to prepare out bamboos, aloes, pineapples, plantains, and other cultivated and wild fibre plants into "half-stuff" for paper, or clean fibre or textile purposes, with a view to their sale in the London or other markets at profitable prices. Unless the boilers could be easily carried to and erected in the neighbourhood of abundant material, the carriage of such material to the manufactory would be costly, even if small crushing rollers were used to squeeze out the large proportion of water contained in plantain stems, aloe, and pineapple leaves, &c.

The process for the manufacture of paper-pulp from wood, bamboos, or any fibrous plants and for separating valuable fibres such as reed, jute, hemp, Manila hemp, flax, &c., &c., from the green ripe stems, is said to be "simple and inexpensive." Let our readers judge from the details given:—

The process is simple and inexpensive, and consists of placing the substances to be treated in a cylinder and subjecting them to boiling under a pressure of 90lb. of steam, in water containing so much sulphurous acid, more or less in combination with an alkali or base, as shall be necessary to prevent the oxidation of the organic matter.

To insure perfect success the base must be such as forms tolerably soluble compounds with sulphurous acid. Potash, soda, and magnesia are available for this purpose; the latter is the best and cheapest, and is principally chosen by Mr. Ekman for his process.

Sulphur and magnesia are therefore the only chemicals required. Necessary buildings and apparatus for the manufacture and manipulation of chemicals cost about £1,000.

To make stuff for 800 tons of paper per annum would require 4 boilers, each 12 feet long by four feet in diameter. One such boiler costs, with lead lining supports and fittings complete, about £500 or £600, erected, and would boil at one operation sufficient wood, &c., to produce 5-12ths of a ton of dry paper-pulp or cellulose, and a boiler can make two boilings a day.

A cylinder, 16 feet in length by 6 feet in diameter, lined with lead, would be sufficient to turn out two tons of dry cellulose every 24 hours; and this would be sufficient to keep running large paper works such as Mr. Ekman's at Ilford. This cylinder would cost £1,000. The smaller cylinders are probably more suitable for India.

Paper works such as Mr. Ekman's cost about £10,000.

The space required for joint factories, i.e., paper and cellulose or fibre-cleaning, would be about 2 acres. An ample supply of pure water free from iron is required for washing purposes; should iron exist in water at a suitable site for manufactory, it can be precipitated by the use of caustic lime.

Pure cellulose or "wood pulp," and "ultimate fibre" are all produced by the same apparatus, and Mr. Ekman's is the only process by which the most or "ultimate fibre" is produced. The great advantages of the process consist in its simplicity, cheapness, and the non-injury and non-discoloration of either pulp or filaments. To paper filaments and ultimate fibre, prolonged boiling and washing alone is required. But the preliminary arrangements

for the preparation of wood and fibrous plants differ considerably, and depends on whether paper-pulp, ultimate fibre filaments, or fibre such as aloe or coir is to be made. Wood will require different preliminary treatment from hemp, and bamboo from reed. After the raw materials have undergone the patent process, the treatment must be entirely different for paper-pulp for filament and for ultimate fibre! If therefore a manufactory is to be economically erected and worked, it is necessary to determine beforehand the class of raw material which is to be treated, and the class of fibre to be produced.

Paper-pulp requires heating and washing; ultimate fibre requires thorough washing; filaments require washing, drying, scutching, and heckling. Again, to sub-divide paper-pulp making; if it is intended to make only ordinary printing papers, small bands, and wrappers, no arrangements for chlorine bleaching will require to be made in the paper-mill; but to make superior sorts of paper as well as inferior, then arrangements must be made for bleaching by hypochlorite of lime. It is not possible to give any idea of the cost of gear and amount of room necessary to prepare a certain quantity of raw material for the patent process until the kind of raw material is defined.

Plans and specifications for the erection of paper mills, or for an apparatus for the preparation of wood or fibrous plants only, can be obtained by sending to the agents at any of the principal towns in India the following information with reference to paper-manufacture:—

- 1.—The kind of raw material it is intended to use.
- 2.—The quantity of paper intended to be manufactured per week or month, and the sort of paper required.
- 3.—An exact plan of the locality where it is proposed to erect the mill, with sections.

As regards fibres for textile purpose—such as the fibre got from hemp, reed, Neigherry nettle, Manila hemp and other numerous fibre plants which abound in India—if a good fibre can be produced from any of this by any process, better can be produced by Ekman's process, and at less cost. If fair sized samples of raw material are sent to Mr. Ekman in London, an opinion will be given—

- 1.—As to whether they will prove useful at all.
 - 2.—As to whether they are best suited for paper or textiles.
- The right to manufacture paper-pulp by Ekman's Patent Process can be arranged for, subject to the payment of a royalty of £1 per ton of dry pulp produced.

The royalty on the manufacture of filaments and ultimate fibre will be somewhat higher and will be especially arranged through the agents—Hinde and Co., Agents, Calcutta, Malabar.

Looking at the abundance and the cheapness of white fir in Europe and the low rate at which it can be converted to paper, we do not suppose any one in India or Ceylon will think of modelling with timber woods. Bamboo is in a different category, and if the matured stems, instead of the young shoots as desiderated by Mr. Routledge could, by Ekman's process, be converted into half-stuff, we should think the manufacture might in many localities, especially on the banks of rivers, be profitably undertaken. It is probable, however, that Government authorities would insist on sowing or planting operations sufficient to prevent the extirpation of bamboo forests. In the case of aloe, pine-apples, plantains, &c., the longer and finer fibres would probably be prepared for textile purposes, and the shorter fibres and waste would answer for paper. "Simple and inexpensive" as Ekman's process is said to be as well as effectual, we suppose it is neither simple nor inexpensive enough to meet the conditions laid down by the Government of India, or the Rs. 50,000 prize offered for the best machine for cleaning reed fibre would be claimed. If we recollect aright, perfect portability was insisted on. Mr. A. Dixon will be able to say if carbonate of magnesia could be easily and cheaply separated from the dolomite limestone which occurs in our mountain regions, and the value of which for agricultural purposes is, we believe, deteriorated by the proportion of magnesia present in its composition. Had sulphate been the form of magnesia required, there would have been no difficulty. The salt manufacturers of India and Ceylon would gladly see utilized a product which, from its bitter taste, purgative properties, and extreme tendency to deliquescence, is, to them, one of the greatest possible nuisances. Deposits of salts in ancient lakes, &c., have frequently been objected to, owing to the mistake of first using the layer of magnesia sulphate which covered the pure sodium chloride; while in the Mayo salt mines in India, the grey mineral is composed of magnesium sulphate to no less a proportion than 58 per cent. If chemical science includes a cheap method of converting sulphate of magnesia into carbonate (as we believe is the case), abundance of the latter would be available here and in India. But there appears to be an extensive formation (over 8 or 10 square miles) of native carbonate of magnesia (magnesian) in the Salem district of the Madras Presidency; and it is said also to occur in the district of Trichinopoly, Coimbatore, and Mysore. Apart, therefore, from the cheapness of this agent in Europe, no doubt stores can be gathered or prepared in India, while some of the Indian and Ceylon pyrites might yield the necessary sulphur. We cannot afford space for Mr. Ekman's detailed specification in full, but we quote the paragraphs in which the special merits of the process are described:—

The peculiar character of the invention will be better understood by considering the advantages possessed by it over the usual method in which caustic soda is employed. Instead of using caustic soda, chemicals are employed which have a far less damaging effect on the fibres, and which, especially when magnesia is used, are much cheaper. In boiling with caustic soda, the separation of the fibre from the incrusting matter depends, as is well known, on such matter being rendered soluble by oxidation, but it is impossible to prevent the fibres themselves from being also oxidized

to some extent, thereby weakening and partially destroying them, and diminishing the quantity of pulp yielded by the wood. On the other hand, in the preparation of pulp according to my invention, no oxidation of the fibre can occur when the operation is properly conducted, and the incrusting matter obtained is in the form of gummy matter of commercial value, instead of being converted, as by the old method, into worthless products of the humus type.

Another advantage is that the boiling can be done at about half the pressure required by the usual method, which is of great importance in practice; besides that, the fibre is less liable to be weakened in the process. A third advantage is, that by this method fibre can be prepared which, without any further chemical treatment, is sufficiently white to be used for ordinary kinds of paper, and is capable of supplying a strong good paper without admixture of other fibre. After a subsequent treatment with bleaching powder, it is made suitable for the manufacture of all the finer kinds of paper. This fibre much resembles linen in its physical and chemical properties for paper-making, and is therefore a very valuable material for this purpose.

A fourth advantage is that the solution which remains after boiling contains a gum-like substance which at a small cost can be made to serve as a substitute for dextrine for many purposes, and thereby produce economy in the manufacture. Some portion also of the chemicals used in the solution may be recovered. A further advantage consists in avoiding the injurious effect on vegetation and on animal life produced, as is well known, by spent soda lye resulting from the ordinary method or process.

And, lastly, cellulose of good quality can be prepared at a comparatively low cost by the process hereinbefore described.

Readers interested in the matter can now see whether Ekman's process is simple enough, and also cheap enough, machinery, chemicals and royalty included, to justify them in trying its effects. If not by individuals yet by a Joint-stock Company, we should be glad to see experiments tried. Of fibrous plants a vast abundance is scattered over Ceylon, and a simple and inexpensive, or, if profitable in the end, a costly method of utilizing such plants, would be an immense boon to the colony.—*Ceylon Observer*.

THE WASTE SUBSTANCES USED IN PAPER-MAKING.

AMONG the most interesting of the scientific and technical lectures delivered during the past month was that by Mr. P. L. Simmonds, who discoursed at the meeting of the Society of the Arts on the subject of "The Utilisation of Waste: A quarter of a century's progress." Mr. Simmonds began by saying that though he had often discussed the same subject before the Society, he could not but think that as stock-taking was an important feature, it would be curious and useful to ascertain the progress that had been made in many of the important branches to which he had directed attention since he first introduced the subject to the Society twenty-eight years ago. In the last quarter of a century, very important progress had been made in our home industries and foreign commerce; but certainly the success that had been effected in the utilising of waste products and developing neglected ones was not the least remarkable of recent scientific advances.

Mr. Simmonds then proceeded to deal with animal waste; the former waste of meat in New South Wales and Victoria, when sheep were boiled down simply for their tallow, and the recent development of the preserved meat trade and the transport of foreign meat to Europe. The use of horse-flesh as food was not left unnoticed, and much stress was laid on the enormous waste of portions of animal food that still goes on in the United States.

Of course the manufacture of "shoddy" and "mungo" from a mixture of woollen rags with wool or cotton received attention, as well as the manufacture of waste silk. The adaptation of skins of fishes as well as of animals for various articles, and the adoption of other waste animal substances as manures was touched upon, and then Mr. Simmonds came to consider the subject of

Vegetable Waste,

in respect to which he stated, referring to paper manufacture, that:—Let us pass now to vegetable substances, and I will first consider the paper manufacture. A recent estimate was published, which set down the paper mills of the world at 4,000, producing 1,000,000 tons of paper, of which the half was used for printing.

The quantity of paper of different kinds now made in the United Kingdom probably exceeds 350 million pounds annually. The newspaper press alone has made enormous strides, to say nothing of books, periodicals, and other printing demands. A quarter of a century ago there were scarcely twenty or thirty daily issues of newspapers in the Kingdom; now there are at least 140, many of them papers with very large circulations.

In 1856 we received but 10,284 tons of rags for paper-making from abroad; in 1881 we imported 26,772 tons. Esparto grass was only introduced to any extent in 1861, when 661 tons were received. In

1881 the imports had risen to 192,493 tons, valued at \$1,240,211. Besides this we also imported 45,550 tons of wood pulp and other paper-making substances.

It is now evident that the future of the paper industry will in a large degree depend upon the use of wood which is already so extensively employed. For the ordinary varieties of paper ground wood is used, but for the finer sorts chemically prepared wood fibre or cellulose is employed. The practical process for the preparation of cellulose was discovered in 1852, and numerous other processes or improvements have since been invented. It comes into commerce in two forms—wood pulp in sheets or blocks, and ligneous meal or wood flour.

In Central Russia aspen wood is most extensively employed; in Sweden and Finland spruce and fir, which afford the longest fibres; in Germany, France, and Belgium mixed woods. The pulp from beech and birch woods has too short a fibre.

About twenty years ago some of the American papers used the bamboo largely for making paper. This is no new application, for the Chinese have long employed it for a common description of paper. Of late years, however, Mr. Thomas Routledge, of the Ford paper mills, Newcastle, who was the first to utilise extensively esparto grass, has prosecuted extensive researches and enquiries, so as to extend the supply of this excellent paper material. It may be mentioned here, that the number of the Society's *Journal* (November 28, 1850) containing Dr. Royle's paper on Indian fibres, was printed on paper made by Mr. Routledge, entirely of esparto.

The fibrous stem and leaves of the plantain, which is so plentiful in most tropical regions, have not yet been practically utilised, although efforts were made some years ago in British Guiana by a Company. Dr. King, the Colonial Botanist at Calcutta, recently reported:—"It has been found that during the dry months, simple exposure of the sliced stems to the sun is sufficient to prepare the fibre for paper-making, provided the paper mill be on the spot. What is still wanted is some cheap mode of removing the cellular tissue, so that the fibre may be shipped to England without the risk of fermentation on the voyage."

A good deal of the jute sent from India to the United States consists of the dark root, or but-tends of the fibre, which are cut-off when the jute is pressed into bales. These are called "cuttings" in Calcutta, and with us, "rejections"; they now form a regularly quoted article of export to America, where they are employed in the fabrication of various shoddy stuffs. In former years these cuttings were thrown away.

The *Dundee Advertiser* of the 14th May 1873 was printed on paper made from jute, and in the issue it was stated:—"This is the first paper, as far as we are aware, ever printed on jute. Being in the centre of the jute manufacturing district, we have been anxious, for some time, to print on the material which has now become the staple of our local manufactures, and we are indebted to our principal paper-maker, Mr. D. M. Watson, of Beilstonfield, for carrying out our wishes. It may be explained that this sample is made almost entirely from old jute bagging." To some extent, jute bagging and waste have now been used by paper-makers for several years.

Other waste substances are coming into use with the paper trade, where obtainable in quantity and cheap. Megass, the refuse stalk of the sugar-cane, makes excellent paper. The husks of oats, barley, rye, and rice are also used alone, or combined with other materials.

Straw-board, of late years, has been found to be a cheaper material than the old fashioned "paste-board," and it has come extensively into use in America for paper boxes. The annual product of straw-board in the State is from 35,000 to 40,000 tons.

Straw has long been employed as a paper material, but it is often scarce and dear. It is even found profitable to buy up the bedding litter from the metropolitan stables, and, after washing and disinfecting it, to sell it to the paper mills. The last United States census (1880) showed that more than 270,000 tons of straw were used for paper.

By the patent process of Chadwick and Clench, the carbonate of soda is recovered from the waste liquors, resulting in the redemption of fibrous materials when manufacturing paper pulp from straw, esparto grass, hemp, jute, and other fibrous materials.

In a paper read last year before the Scottish Society of Arts, by Mr. G. J. Wishart, on the recovery of soda from the spent lye of the paper-maker, he observed:—

"The industrial progress of recent years has in no direction been more marked than in the utilisation of waste materials. New industries have thus been created, and old ones rendered more profitable.

* The whole materials used were:—

| | lbs. |
|--------------------|---------------------|
| Straw | 540,843,600 |
| Rags | 418,417,480 |
| Old paper | 198,248,000 |
| Manilla stock | 186,523,000 |
| Cotton-waste | 26,508,000 |
| Corn (maize) stock | 2,098,100 |
| Esparto grass | 587,800 |
| | <hr/> 1,369,511,400 |

This is inclusive of the wood-pulp consumed.

while galls public nuisances have, in many cases, been removed or abated.

Were it not for the bye-products obtained from what was once considered waste in the manufacture of paraffin oil, it would be impossible for the manufactured oil of this country to compete with the ready-made article of the American wells. By a similar utilisation, gas—the product primarily sought for in the distillation of cannel coal—can, it is said, be manufactured free of cost; while, in the paper industry, the chemicals employed in the process of converting esparto and other raw fibrous substances into paper pulp are now, to a large extent, recovered, and are thus kept out of the streams they formerly polluted, to the manifest profit of the manufacturer, and the satisfaction—so far—of riparian proprietors.

Until a very recent period, the waste paper of the Government offices of London was the perquisite of the messengers. But when it was found that the aggregate sale of this waste paper reached the sum of £10,000 to £15,000 a year, it was thought time to look into this, and it was then handed over to the Stationery office, and, in the last financial year, the sale of waste paper reached £11,771. Unfortunately, the Government printing is very lavish, every member receiving about a ton weight of Parliamentary documents yearly. The United States Treasurer sells yearly more than 600 tons of paper pulp resulting from the destruction by maceration of Government securities, bank-notes, &c.

In one large printing and publishing establishment in the metropolis, the waste paper in shavings and imperfect impressions exceeds 75 tons a year. Even the newspaper offices now economise and use up their spoiled impressions or overplus papers for printing their posters on.

Mr. Simmonds then went on to consider the utilisation of fibres for brush-making of seeds for producing oil, beet-root pulp for feeding cattle, the molasses of beet sugar for alcohol, and the residue liquor, or "vinasse," for making potash. He then went on to speak of waste substances of the brewery, and numerous other vegetable substances, and concluded with an interesting reference to mineral waste, including broken glass.

In the ensuing discussion Mr. Roulledge said the paper trade was probably the one which, of all others, utilized waste products more than any other. They utilised cotton waste, flax waste, hemp waste, jute waste, old ropes, canvas rags, and even, as had been said, stable manure—and he had seen very respectable paper made from that material; they also used spent tan. In fact, the paper manufacturer could use any vegetable fibre whatever, sometimes adding a little animal fibre to give greater strength. Amongst other materials in connection with the silk industry was mulberry bark; it was customary in all silk-producing countries to grow the mulberry leaves on the young branches of the trees, and when these were stripped they were cut down, and had hitherto been burned. Some time ago he tried to collect them in Italy, but found it cost too much; there was, however, an immense quantity to be obtained in India, and it would, he believed, produce paper equal to what Japanese made from the paper mulberry. He had been astounded at the statement in the paper of the enormous quantity of maize wasted in the United States, but could readily believe it, for some years ago, having made an excellent quality of printing paper from maize leaves, he took out a patent for it in the States. When he got there, however, he found the cost of collecting the leaves was so great as to render the process practically unworkable. In some places they actually burned the corn to get rid of it. Allusion had been made to the fact that, in 1856, when Le introduced esparto, the *Society's Journal* was printed on paper made from it; and he might add that the year before last a portion of one issue was printed on paper made from bamboo. Asbestos had also been used in paper making, and would be very valuable in some cases, because an unflammable paper could be made with it. He had some very fibrous asbestos which could be used admirably for what they called a "filler-up." A considerable deal of attention had been given to the utilisation of the plantain tree and banana for paper-making, but his experiments had shown that it contained so small an amount of fibre that he did not see how it could pay. The stems of these herbaceous plants contained 80 to 85 per cent. of water, besides a large quantity of mucilaginous and gelatinous matter which must be eliminated, or else fermentation would set up; so that, practically, he did not get much more than three to five per cent of fibre. He had made excellent paper from Manila hemp in the shape of old rope, and, in fact, the whole of the greenbacks introduced by the Americans after the civil war were made from this substance. He had bought hundreds of tons at £2 to £3 a ton, but the present price was £12 to £13. It was collected by the Americans and exported, because they found that by chemical means they could bleach it and make magnificent paper material. This hemp was produced by slave labour in the Philippine Islands at a very low cost, and sold here as a semi-manufactured fibre at £25 to £30 a ton for rope-making, and also for making hangings, because it took bright coloured dyes. After being thus used, it came as a waste product to the paper-maker. Jute waste was also used to a large extent; and to-day, although the importation of esparto grass was very large, probably reaching 200,000 tons, without these waste products consumers would not obtain the cheap paper they did, or the cheap periodical which were the result of cheap paper. Wood pulp was likely to assume very considerable importance in the paper trade, two or three new processes having recently been introduced, by which pine wood could be converted into cellulose. He had samples of paper made from it, of wonderful strength and tenacity, very much like parchment. This cellulose could be made in two ways, either by boiling the wood with caustic alkali, or by treating it with sulphurous acid; and when the pulp was manufactured you could hardly tell one from the other. He had recently inspected the process in Sweden, and found the results very extraordinary; but it could hardly be called utilizing a waste product, though a large quantity of material was made use of which otherwise would not be of much value.

THE MANUFACTURE OF PAPER PULP BY MEANS OF SULPHUROUS ACID COMBINED WITH A BASE OR OTHERWISE.

(Translated from the *Journal des Fabricants de Papier*.)

SEVERAL patents have lately been taken out in France by foreigners for the treatment of ligneous and textile materials by sulphites of lime, soda, potash, and magnesia, with the object of converting these materials into paper pulp.

In the interest of French industry, and likewise in some degree for its reputation, we consider it a duty to publish in *extenso* the description of a patent No. 116,996, taken out the 12th February, 1877, by M. Lioud, a paper manufacturer at Bourg Argental (Loire).

We shall describe this by extracts, in order of their dates, from the patents taken out in France by M. D. V. Francké, the 13th October 1881; by M. M. D. Ekmann, the 10th November, 1881; and from that obtained in Germany, and not in France, by M. Mitscherlich, the 23rd January, 1878—patents all having the same object, claiming directly or indirectly the treatment of vegetable materials, principally wood, by sulphurous acid combined with a base, for the production of paper pulp.

If these several inventors, of whom we neither suspect the good faith nor merit, have already been able to profit by their discoveries in their own countries, and can also profit like other inventors in ours, by coming here to manufacture their paper pulp according to this process, they cannot pretend to demand any remuneration for the invention itself from those who are equally entitled to make use of it, because a remuneration of this kind can only be due in equity and justice to the real inventor as a legitimate reward for his labour and sacrifices.

The patent of M. Lioud is lost, failing the regular payment of the annual tax legally required. If its author has no longer the exclusive right to work in France for his sole profit, this patent for the treatment of wood and textiles by sulphurous acid alone, or combined with different bases to produce paper pulp, and this because he has abandoned it voluntarily, for reasons which we need not enquire into, it is only right that we should give him the credit due to his invention, and that France as well as foreign industry should profit to the utmost extent by the fruits of the invention of one of its countrymen, and this without paying tribute to foreigners who may lay claim to the merit of the same inspirations as the original inventor, only somewhat later on.

Patent No. 116,996, 12th February, 1877, by M. Lioud. Title: *The separation of woody and textile materials generally, and their conversion into paper pulp.*

In order to render both woody and textile fibrous materials suitable for the production of paper, it is necessary to break up and destroy the combination which unites their fibres together. In effecting this, however, it is essential to preserve a certain length to the ultimate fibres, while at the same time rendering them fine and supple, failing which the proper degree of felting together cannot be maintained, this being essential, in order to produce a good sheet of paper.

By certain mechanical means at present employed, the fibres can be reduced in length, but they still remain coarse and thick; chemical processes, which are daily extending, have the merit of removing from the true cellulose all, or a considerable portion of its incrusting compounds, of separating it, and rendering it supple and fine, while at the same time preserving its length.

The treatment which is the object of this patent consists in the disintegrating chemical action of solutions of sulphurous acid, either alone or more or less combined with different bases. The operation consists in digesting woody or textile materials in these solutions at a temperature more or less elevated and prolonged, according to their respective character, and thus is obtained a product sufficiently disintegrated to felt in a suitable manner, after mechanical treatment, for the manufacture of card-boards or paper. The pulp thus prepared may be employed either for carton or paper.

I claim the treatment of fibrous substances by submitting them, according to their character, to the disintegrating action of solutions of sulphurous acid, more or less concentrated, either alone or combined with bases, and at a temperature more or less prolonged and elevated, a process which renders them fit to be converted into paper pulp by a subsequent mechanical trituration.

Patent, D. V. Francké, No. 145,317, 13th October, 1881: *For an improved process of manufacturing paper pulp.*

According to this specification, a solution of sulphite of lime with sulphurous acid is prepared by causing the vapours of sulphurous acid, produced by burning sulphur or roasting or calcining sulphides such as iron pyrites, to pass up a tower packed with limestone kept moist by a flow of water.

It is in this solution at 4 or 5 degrees Beaumé, that the materials to be treated are boiled under a pressure of from 4 to 5 atmospheres during 12 to 15 hours.

M. D. V. Francké claims as his invention the production of paper pulp from wood, esparto, from corn, maize or other straws, or from any other suitable fibrous materials, by treating them with an acid sulphite of lime prepared and applied as he describes.

An additional certificate, dated 21st December, 1881, follows:

This patent commences by declaring, having now found that the acid sulphites with other alkaline earths, such as magnesia or the soluble alkalies of soda and potash, are also applicable to his process, and he describes the method of preparing such solutions.

For an alkaline earth such as magnesia, or a mixture of magnesia and lime, the process is the same as for lime: to treat a soluble alkali such as soda or potash, he fills the tower with some inert material, porous, however, such as coke, bricks, or porous stone, and while the sulphurous acid vapours traverse the tower from bottom to top, he percolates or pours over the porous material an aqueous solution of the caustic alkali. The liquid collected at the bottom of the tower is the sulphite of the alkali.

In this additional patent, M. D. V. Francké claims as his invention:

The method of extracting from alkaline earths or from an alkali a sulphite applicable as a dissolvent for the production of paper pulp. 2nd: The manufacture of paper pulp by treating wood, straw, or other vegetable fibres by acid sulphites of an alkali, prepared, and applied essentially as described.

Patent, Daniel Eckmann, No. 145,744, 10th November, 1881.

Title: *Improved method for the treatment of wood in order to obtain fibres suitable for the manufacture of paper.*

The following is the description of this process, having for its object the production from wood of a fibrous pulp suitable for the manufacture of paper and other purposes. It consists in digesting wood under pressure in a solution of sulphurous acid and magnesia under certain conditions described.

Potash and carbonate of soda may also be employed, but the inventor prefers magnesia, because it is more advantageous, and possesses chemical properties which render it peculiarly suitable for this process.

It is therefore upon the hypothesis of the employment of magnesia and the wood of white pine of good quality and fine grain the following description is based.

The wood, deprived of its bark and its knots removed, is cut into pieces 15 to 20 millimetres in length, and crushed between two rollers so that the solution may readily penetrate it; this preparation, however, may be otherwise effected.

White pine, and the other woods of this species, are particularly suited to be treated by this process; they afford for the manufacture of paper fibres long, strong, and very pure, resembling in character those of hemp. This species of wood is very abundant in all countries, and generally cheap.

The suitability of other woods for this purpose depends chiefly on the length and quality of their fibres, and upon the greater or less facility with which their incrusting compounds are dissolved. The choice of wood, therefore, is determined by the purpose for which the pulp is to be employed.

It is desirable in general to avoid employing very resinous woods, on account of the difficulty of sufficiently dissolving the various incrusting compounds in order to produce good cellulose. The wood is sorted with more or less care, according to the pulp which it is desired to produce: when a superior quality of pulp is desired all resinous pieces, also those which are hard or decayed, are rejected.

The wood thus selected is sorted over as required, and filled into a boiler with a double jacket, lined in its interior with lead, and so arranged as to turn on its transoms to facilitate charging and discharging.

It may be a vertical cylindrical boiler, 1·200 m. diameter (4 feet) by 3·000 m. (14 feet) high. The boiler is filled with wood to two-thirds its height, and the solution should cover the contents, so that during the whole period of the operation the contents should be

always covered, still leaving sufficient space for steam. A plate of lead pierced with holes prevents any rising of the materials. The cover is then secured by a steam-tight joint. The boiler is also furnished with a valve or stopcock to be regulated by the hand.

In the preparation of the ley it is desirable to obtain a solution containing about two equivalents of sulphurous acid for one equivalent of magnesia, or approximately in the proportions necessary to constitute a double sulphite, or the salt known as bi-sulphite of magnesia. The solution then contains very nearly 1·4 per 100 of magnesia and 4·4 per 100 of sulphurous acid.

The steam is introduced into the jacket, to begin with, at a pressure of 10 to 15 lb. per inch: so soon as the pressure in the interior of the boiler attains 5 lb. per inch, the stopcock is slightly opened to permit of the escape of a small quantity of gas and steam. The pressure in the jacket is increased gradually as the pressure in the interior boiler increases, and it is recommended that the excess pressure in the first shall not exceed that in the second more than 30 lb. per inch (two atmospheres 1·10").

As the pressure in the inner ley boiler increases, the escape of gas and steam should also be increased, to avoid either the burning of the discoloration of the wood.

In a boiler of the dimensions described the operation should be conducted in such a manner that the pressure in the ley vessel reaches 25 lb. in two hours, and that it increases 20 lb. per hour during the two succeeding hours, 15 lb. during the next hour, and 10 lb. per hour during the following two hours. When the pressure reaches 85 to 90 lb., this is kept up a further three hours, when the operation is finished, this being proved by a peculiar smell given off by the gases which are allowed to escape through the blow-off cock.

In the event of the wood becoming charred or discoloured, which is indicated either by the characteristic odour of the gases allowed to escape or by the colour of the ley, the further admission of steam is arrested, the boiler is emptied, and the wood washed.

When no burning of the wood is indicated, it may be allowed to remain some time longer after the admission of steam to the jacket has been stopped, the boiler is then emptied and the wood drained. The resulting pulp is triturated and washed, as usual, and the ley, by suitable treatment, furnishes a gummy substance which in many cases may be used as a substitute for dextrine. It may also be treated to recover the chemical agents that have been employed.

When it is desired to produce a pulp of lower quality, by abstracting a less quantity of combined compounds, a ley less concentrated is employed at a lower pressure.

The proportions of the elements of the ley may be varied, noting, however, that the solution of the incrusting compounds will be less complete the more basic the ley, and the production of the pulp much more readily attained the more acid the ley.

It has been remarked that the pressure should not exceed 85 to 90 lbs per inch, because within these limits good results are attained, and a higher pressure would not be desirable in an economical point of view; these limits, however, are not absolute, as good pulp has been obtained when the pressure has been carried to 110 lbs or even higher—8 atmospheres or more.

The pulp thus produced is suitable for ordinary printing papers, and when treated by chloride of lime, for papers of finer quality.

The ley, which is of an amber color, contains a large quantity of gums resembling dextrine, and some other soluble substances, susceptible of being more or less utilized.

When the separation of the compounds incrusting the cellulose is less complete, the pulp is suitable for papers of inferior quality, for carton, and for papier maché.

The process is readily employed for other woods besides white pine, with suitable modifications. The quality of the pulp will always depend, within the limits stated, upon the suitability of the wood employed for the manufacture; thus, very resinous wood, although its fibre may be very good, is only suitable for inferior papers, on account of the difficulty of abstracting the incrusting compounds.

The peculiarity of this process for the manufacture of pulp consists in a consideration of the advantages it possesses over the customary process with caustic soda.

Instead of soda, materials are employed which have much less action upon the fibres, besides which they cost much less, especially when magnesia is employed.

By the soda treatment, the separation of the incrusting compounds from the fibres depends upon the former becoming soluble by oxidation; but the cellulose is also at the same time inevitably oxidised, the fibre thus loses its strength, and the yield of pulp is also less.

When the new process is judiciously conducted, no oxidation of the fibres can be produced, and the incrusting compounds are obtained in the condition of gums, which have a commercial value, instead of being of no value like those resulting from the soda process. Another advantage derived is, that the treatment of wood by the bi-sulphite of lime only requires half the pressure necessary by the soda process. A third advantage is, that the pulp produced by this system is sufficiently white, and can be employed, without other chemical treatment, for ordinary white papers, and affords, without any addition of other fibres, a good and firm paper. If the pulp is bleached by means of chloride of lime, it may be used for all fine papers.

The pulp evidences in its conversion into paper physical and chemical properties analogous to those of hemp; it is, therefore, suitable for similar purposes. A fourth advantage results from the leys, after the boiling, containing a gummy substance, which at low cost may be converted into a substitute for dextrine; a portion also of the materials employed for the ley may be regenerated.

A still greater advantage is, that the process has no influence either on animal life or vegetation, while such is not the case with the process employing soda.

Finally, the cellulose is of excellent quality, and can be produced at a comparatively low cost.

M. Mitscherlich, of Munden, has taken out in Germany a Patent dated 23rd January, 1878. Title: *Novelties in the processes of extracting tannin, with recovery of the bi-products, cellulose, gum, acetic acid, double sulphite of lime.*

Description: The process consists effectively in the action of double sulphite of lime, or sulphite of lime dissolved in a solution of sulphurous acid, upon vegetable substances previously digested by steam, for example: wood, at a temperature above the point of the ebullition of water.

In what follows, wood alone will be referred to, although the process is equally applicable to all other plants.

The solution of double sulphite of lime is obtained by causing to pass simultaneously through carbonate of lime, reduced to pieces of medium size placed in a tower, a current of water flowing from the top to the bottom of the tower, while a current of sulphurous acid gas is caused to pass in the reverse direction.

The sulphurous acid is produced partly by the burning of sulphur, or other sulphur mineral, and partly by the evaporation of a solution obtained as hereinafter described; in the same manner, other sulphurous salts, such as sulphite of soda, may be obtained at low cost, which can, under certain conditions, be equally employed for this process.

The wood with the bark taken off, cut by a saw into pieces of suitable length, either with or without the knots, is placed in an iron boiler covered with cement and lead, furnished with heating tubes, and the necessary apparatus for the entrance and exit of liquids and vapours. The wood is first submitted to the action of steam, and then boiled in the solution of bisulphite of lime, a shorter or longer time, according to its state of division, but at least during eight hours, at a temperature of 180 deg.

During the process, the compounds which are not cellulose are dissolved in the solution, the latter remaining as a softened mass. The contents of the boiler are then submitted to evaporation so long as the vapours escape, and they are conducted into the tower containing the carbonate of lime previously mentioned, still bearing the smell of sulphurous acid. These vapours may also be conducted into a reservoir containing water and pure slacked lime, and thus may be obtained a concentrated solution of bi-sulphite of lime, the use of which is extending more and more for preventing the fermentation of acetic acid and other non-fermentable compounds.

If the carbonate of lime is replaced by carbonate of soda, soda-salts of different degrees of acidity are readily obtainable. The solution in which the cellulose remains is then drawn off. It contains besides the salts of lime, plaster, &c., tannin, gummy matters, acetic acid, and a little sulphurous acid. Up to the present time it has chiefly been employed as follows:—

- (a) As a material for tanning skins.
- (b) For the manufacture of gum.
- (c) For producing vinegar.
- (d) The solution may, without any other preparation but concentration, unless employed where it is produced, be used for tanning, because the bi-products, other than tannin, which it contains, have no damaging effect in tanning.
- The tannin may likewise be precipitated by lime, and separated after a given time from the dried precipitate by means of an acid.

The patentee remarks that the small quantity of sulphurous acid contained in the solution expedites the tanning process and increases the solubility of the bi-products in the solution. The tanning matters of the solution, when it is employed as it is produced, retain the properties of the bark of the wood from which they are derived. If, for example, the wood is pine, the natural colour of the skins will be as little changed as if the bark itself were used, but the colouring action is modified in certain cases when the solution has been treated by lime and acid as previously described.

(b) For the manufacture of gummy products, the solution is simply evaporated, the sulphate of lime crystallised, and separated by decantation. The residue of a brown colour, very deliquescent, replaces in many cases gum-arabic.

The residue dried in the same manner as the concentrated solution can be kept indefinitely without any trace of decomposition or mouldiness. For some purposes it is desirable to precipitate the lime by sulphuric acid, and to separate the sulphurous acid disengaged by evaporation, or to convert it into sulphuric acid by the addition of an alkaline chloride. For other purposes, it is necessary before using the gum to eliminate the tannin.

(c) The acetic acid is obtained by condensing the vapours which are disengaged during concentration. Alcohol may be obtained by the fermentation of a portion of the solution.

The insoluble portion which remains in the boiler is the cellulose, with a part of the knots of the wood, the condition of which is but little altered on account of their density, and which may then be readily separated by mechanical means. The cellulose, nearly white, is obtained by this new process in much larger quantity than hitherto: thus, for example, pine-wood, air-dried, will yield 66 per cent of cellulose. This is fit to be employed direct, or after having been bleached, for the manufacture of paper, and even for the production of tissues.

The advantages of this new process over those now in use are, that it requires a less minute division of the wood, a temperature and a pressure so low that the boiler is not affected, and that all chance of explosion is avoided. The preliminary digesting in steam materially facilitates the reaction of the bi-sulphite of lime on the wood. The yield of cellulose is greater.

The patent, the description of which we have just read, has evidently for its principal object the manufacture of *paper pulp*. The assertion that the yield of cellulose from air-dried pine should be more than 66 per cent is specially to be noted, as it has been considered till to-day that no wood has given more than 40 per cent yield. If by Mitscherlich's process 66 per cent or more is obtained, it is possible the pulp obtained is not pure cellulose, but contains a large proportion of the incrusting compounds of the wood, transformed and bleached.

It appears from the circular of a manufactory employing this new process that the unbleached pulp may be employed for white paper without any other preparation than an energetic washing by plain water.

To avoid any accident when sizing, it is desirable to add before doing so a small quantity of bi-sulphite of lime. This compound, which constitutes according to the previous description the basis of the manufacture, can be delivered from the manufactory in solution, in carboys, or casks preserved by petroleum.

In the event of a higher white colour of the pulp being desired, this may be obtained by treating with chloride of lime. It is recommended when doing this for economical reasons to add a small quantity of milk of lime. The reason for doing this is not explained.

This process, for which no patent has been taken out in France, has been employed in Germany before either M. Francké or M. Eckmann made application for their patents.

CINCHONA.

THE CINCHONA TRADE.

IT is a frequent remark that there must needs be a limit to the demand for, and consumption of quinine; and it is argued that those who are planting cinchona largely, in confident expectation of the maintenance of present market values, are likely to be caused severe disappointment, when they commence to reap their harvest of bark. The Madras, Bengal, and Netherlands India Governments have undertaken the cultivation of cinchona, not in view to making a profit from it, but primarily in order to render cinchona more

FORESTRY.

TREE PLANTING IN BENCOOLEN.

BATAVIA.—During the month of November last, the authorities at Bencoolen made praiseworthy exertions in planting useful trees, the success of which will greatly benefit the population of that residency now in such a backward state. It is almost incredible that the *asam* or tamarind, so indispensable in Java cookery, is so scarce in Bencoolen that it has to be imported from abroad for the consumption of the people. In the compound of the Resident's dwelling, three nurseries of tamarind seedlings have been laid out, with the object of planting them on the roadsides where now either worthless trees or none at all grow; thereby glorious shade and charming lanes will be secured. About 1,000 Banda nutmeg seeds have been sown hitherto with successful results. It is intended to distribute the plants from them among the population to replace the too old and dead trees in the many but sadly neglected nutmeg plantations there, whereby it is hoped to raise from its present declining state the cultivation of that product which formerly was a source of abundant profit to the people. A similar experiment, says the official *Java Courant*, will be made with seeds of the Banda *kanari* trees from whose hard fruit, eaten like hazelnuts, a pleasant oil is extracted.—*Java Bode*.

THE PROTECTION OF FORESTS.

THIS matter forms the subject of an article in the current number of the *North American Review*, written by Professor Sargent. It has reference especially to North American forests. After alluding to the difference in the forests of the Atlantic, Central, and Pacific regions respectively—differences with which our readers are familiar from the writings of A. Gray and Hooker—Professor Sargent goes on to remark that "the distribution of the forests over the continent shows that where the rainfall is heaviest, the forest growth is heaviest; that where the rainfall is light and unequally distributed, the forest is proportionately light; and that where the average annual rainfall sinks below a certain amount—about 20 inches—the real forest disappears entirely. Speaking of the maintenance and reproduction of forests, it is truly stated "that a forest in which a regular succession of young trees is not coming on is always in danger of speedy and entire destruction." Fire is the greatest enemy to the American forest; next to fire, the browsing animal inflicts upon it the greatest damage; and the American people, in generally using their woodland for pasturage, have adopted the surest method to compass the final destruction of their forests. In spite of this, the unequalled forests of fir of the north-west coast hardly show the marks of thirty years of cutting and annually increasing fires. In this humid climate young trees of the same valuable species spring up so quickly on land stripped of its original forest covering, and these new forests grow with such remarkable rapidity, that there is little danger of their final extinction. Serious and often fatal injury has been inflicted on the Sierra forests, however, by the sheep which every summer are driven up by thousands to pasture in the cool moist subalpine meadows of these high mountains. The sheep, encircled by great bands of horses, cattle, and goats, clean everything before them—nothing but the large trees and the most stubborn and thorny "chapparal" escape their voracity. Every young tree, every bud, and every blade of herbage is devoured, everything green is destroyed, and the sheep tread out from the dry, gravelly hill-sides the roots of all young and delicate plants. The Sierra forest is over most of its extent a forest largely composed of full-grown trees, containing but few young seedlings, and little undergrowth to shelter and protect them. Its condition, then, is critical, and unless measures can be taken for effectually limiting the range of browsing animals, its total extinction must be merely a question of time. A forest crop is slow to mature, its area cannot be extended or reduced in response to large or small demands. A forest fire may destroy in a single day the growth of 500 years, and will another 500 years can hardly replace. Although the forest does not cause the rain to fall, it hushes it after it has fallen. It serves as a mulch on the earth's surface, it prevents the too rapid flow of water from the surface, checks evaporation, breaks the force of destructive winds, and prevents the soil on the mountain-side from being washed away. The great value, then, of the forest lies in its power to protect the surface of the ground from denudation, to regulate the flow of rivers, modify temperature, and preserve the rain.

abundant, and thereby to bring quinine more readily within reach of the fever-labile multitude. Quinine is not exactly the kind of medicine that one would go out of one's way to indulge in unnecessarily. It is bitter in the mouth; it leaves an acrid taste; and it is apt to make the head swim, and the ears to buzz. But year by year the demand for quinine increases, and this demand has produced a great increase of supply, coupled with the maintenance of a high and profitable range of prices. In 1870 the quantity of cinchona bark imported into the United Kingdom (chiefly into London, which is the chief market for the commodity in the world) was 2,536,568 lbs., valued at £218,565, or at 1s. 8½d. per lb. Twelve years afterwards, or in 1881, the imports amounted to 14,040,096 lbs., valued at 2s. 5½d. per lb., or £1,814,501. Thus the quantity imported increased by over five and a-half times, yet the average market price rose by a half. The importations from India were so small prior to 1876 that they were not thought worthy of special notice, and were included statistically in the quantities received from America and other countries. In 1876 they stood at the modest total of 158,480 lbs., valued at £22,682; in 1877 and 1878 they stood at about half-a-million pound, valued at about £75,000; in 1879 they shot up to 1,004,080 lbs., valued at £148,376; whence they rose in 1880 to 1,814,786 lbs. valued at £216,068; and in 1881 to 1,804,912 lbs., valued at £248,894. So in the six years ending with 1881, the quantity and value of Indian cinchona bark increased by over eleven times. India, however, supplied in 1881 but little more than a sixth of the quantity of bark taken by the United Kingdom. She ranked notwithstanding second on the list, and was followed by Peru—the original home of "Peruvian Bark"—with 1,169,168 lbs., France with 1,067,808 lbs., Ecuador with 1,016,736 lbs., United States with 489,664 lbs., &c. Columbia headed the list with 7,945,728 lbs., valued at above a million sterling, in 1881, as compared with 989,408 lbs., valued at £84,330 in 1870. In 1878, 1879, and 1880, the imports from Columbia amounted to about 2,500,000 lbs., and in 1881 they nearly touched 3,000,000 lbs. The increase was chiefly due to the newly discovered Cuprean Bark. The total imports and exports of the United Kingdom were:—

| Date. | Imports. | | Exports. | |
|----------|------------|-----------|-----------|---------|
| | lbs. | worth £ | lbs. | worth £ |
| 1870 ... | 2,535,568 | 218,565 | 1,431,920 | 123,375 |
| 1871 ... | 2,358,816 | 265,976 | 2,017,844 | 154,180 |
| 1872 ... | 3,186,512 | 288,620 | 2,132,256 | 224,043 |
| 1873 ... | 5,121,424 | 456,066 | 3,274,320 | 311,645 |

The average price per annum was—

| | | | | | |
|----------|-----|-------|----------|-----|-------|
| 1870 ... | 1s. | 8½d. | 1876 ... | 1s. | 10½d. |
| 1871 ... | 2s. | 5d. | 1877 ... | 2s. | 0½d. |
| 1872 ... | 1s. | 9½d. | 1878 ... | 2s. | 10½d. |
| 1873 ... | 1s. | 9½d. | 1879 ... | 2s. | 11½d. |
| 1874 ... | 1s. | 10½d. | 1880 ... | 2s. | 7½d. |
| 1875 ... | 1s. | 9½d. | 1881 ... | 2s. | 7 d. |

The mean average for the twelve years was 2s. 2½d. It is a curious circumstance mentioned by Mr. John Hamilton, of Great Tower Street, London, to whom we are indebted* for these figures, that in 1881 England imported 1,067,808 lbs. from, and exported 1,084,272 lbs. to France. The actual consumption of bark in France rose from 1,764,600 lbs. in 1877 to 4,377,145 lbs. in 1881, and the price from 2s. 4½d. in the former to 2s. 10½d. in the latter year. There are now four quinine manufactories in France, viz., two in Paris, one at Argenteuil, and one at Ivry. Germany imported and used 1,480,000 lbs. in 1877, and 4,769,160 lbs. in 1881; paying 2s. per lb. in the former and 3s. 2d. in the latter year. Italy imported 990,080 lbs. in 1877 and 5,546,240 lbs. in 1881. Mr. Hamilton says:—"A good deal of bark is used in its rough state by the inhabitants of marshy and feverish parts of the country, in addition to the annually consumed by the important manufactory at Ang quinine. I am told that in 1881 as much as was used for the manufacture of quinine alone." Lastly, Holland received from England 2,910,320 lbs. in 1881, from Government plantations in Java 178,286 lbs., and from private plantations 90,244 lbs.; and the United States imported 4,201,372 lbs. in 1881.

We gather from the Administration Report of Madras that on the 31st March 1881 there were 847 acres under cinchona cultivation belonging to the Government with 677,350 plants. Between 1874-75 and 1880-81 nearly three million plants were raised, and the produce in bark rose from 57,250 lbs. to 243,245 lbs. In 1875-76 the Government realised Rs. 60,404 from the sale of bark, and in 1879-80 Rs. 4,24,323. The report does not state the area of land under cinchona cultivation by private individuals.—*Madras Mail*.

* Statistics of Cinchona Bark, by J. Hamilton, London: J. W. Collins, 1882.

TEA.

INDIAN TEA IN KASHGARIA.—The *Bombay Gazette* says:—People who are interested in Indian tea will learn some curious facts in Colonel Kuropatkin's "Kashgaria." Before the year 1864, when the Chinese were driven out of Kashgaria, the inhabitants got their tea from China, along the great trade routes. When this source of supply was cut off, and the stores in hand exhausted, the leaves of an indigenous plant called *surrogatino* were used instead of tea, the infusion being rendered palatable by the help of salt, butter, and milk. Then tea began to be imported from the Russian territory and from India. Chinese tea came in *via* India. Kuropatkin mentions that even at Tashkend Chinese tea is sold which has come from Canton to India, and thence by the Suez Canal to Odessa, and so round to Central Asia. Naturally the Indian tea is much cheaper than Chinese tea coming by such a roundabout route, but it is considered inferior in quality. It is smuggled across the Russian frontier, "to the great disturbance of Russian tea traders." According to a moderate computation, it seems that the Kashgarians would consume about £56,000 worth of tea per annum; the quantity going to them across the Russian frontier amounts to rather less than £4,000. Latterly the Chinese tea is beginning to find its way along the restored trade routes to Kashgaria, and Kuropatkin thinks it will drive out not only the Chinese tea coming round from Canton *via* India and Russia, but the Indian tea imported direct. And it will, he expects, find its way into Russian territory also by the restored routes. "Tea of Indian growth," he says, "however cheap it may be, is less advantageous to us than the Chinese article. At present in exchange for tea we dispose of our manufactures, especially cloth, to China, whilst for Indian tea cash exclusively must be paid." It would be denying a pleasure to Indian tea-planters to omit the very next sentence, in which the writer shows that his particular reason for encouraging Chinese as against Indian teas is about to cease and determine. "Unfortunately of late our [Russian] trade relations with China have become so bad that if we do not adopt measures, China will disappear altogether as a market for our wares, and for China tea we shall then have to pay exclusively in hard cash." As it will take less of this somewhat scarce commodity to buy Indian teas, India will then have a very good chance of getting the supply of the Central Asian market into her hands, provided Kuropatkin's advice to impose "a heavy tax on Indian teas," as well as upon English goods, be not acted upon. Even if it be, there will be room for a considerable extension of the smuggling trade to which that gullant officer refers.

COCOA.

SHAND'S PATENT TEA DRYER AND COCOA CURER.

BESIDES a tea dryer, Mr. Shand claims that his invention, as we have before stated, will be equally efficacious with cinchona bark, and particularly with the curing of cocoa. Various experiments have been tried by Mr. Shand, which all go to prove that, beyond doubt, the sun-drying of cocoa after fermentation can be equally well performed by this machine. About 70 lbs. of cocoa nibs were placed at Mr. Shand's disposal, wet from the pods by the Ceylon Company, and laid about 4 inches deep over the galvanized iron plate or boiler, an equal temperature of about 170 degrees being maintained. We have already described this machine in an issue of a few days ago, so that further details are unnecessary. The object kept in view with regard to this experiment was, whether or not the two processes of fermentation and drying could be amalgamated into one. About three days after the nibs were first placed on the machine they were perfectly dry, and the inside kernel had a very rich, dark, chocolate colour. The system has only one disadvantage, namely, that the outside of the bean was a dark, dirty shade, due to the mucilage having dried on the bean.

Another experiment was tried. On a larger though similar machine a quantity of fresh and wet beans were placed and an equal temperature kept up (i.e., 170 degrees), but the layer of beans was of the thinnest and in a few hours the beans were perfectly dry. The outer skin had, however, split from exudation and the outside of the beans was again dark. In this case, Mr. Shand made some chocolate, which we had the opportunity of tasting about 24 hours after the wet cocoa beans had been deposited in his machine.

With regard to these experiments, one thing is certain, that, whether the fermenting can be amalgamated with drying in one process or not, there is no difficulty whatever in drying cocoa after it has been fermented, so that, if this is established beyond a

doubt, the principal difficulty encountered by the cocoa planter will be overcome. Fermentation, which usually takes about eight days, can always be done in the estate store, and is the simplest thing in the world, all that is required being to heap a quantity of the nibs to gather on the floor, or in a bag, or tub, when in about eight days the whole is completely fermented.

The great and almost insuperable difficulty is that immediately after the fermentation is completed, the beans must be placed at once in the hot sun for the space of three days. Should there be no sun the whole of the picking is lost. It will be at once seen how difficult it is to make certain of turning out a good sample, owing to the fickleness of our wet climate and the immense advantage a machine such as Mr. Shand's has over a combination of meteorological conditions. The inventor is, however, of opinion that, with perfectly fresh beans—of course the beans experimented with were some days old—and a lessening of the temperature to about the point where natural fermentation stops, say, 120 degrees, the same effect will be produced; and, as a consequence, no two processes will be required. We recommend cocoa planters to purchase a small model machine from Mr. Shand. It can be obtained with full directions for use, is quite as good a test as a larger and more expensive machine, and can be heated by a kerosene oil stove placed at one end.

Tea has been successfully fired on this machine, and though large and more extensive experiments are requisite before pronouncing definitely as to its complete success, we have but little doubt it will prove to be as useful and efficient as other machines, while irrespective of the advantage of its cheapness, it has excellencies of its own which, should they be confirmed by similar results on a larger machine and more extended scale, cannot fail to bring the patent into general use.

TOBACCO.

TOBACCO IN BORNEO.

ACCORDING to a Samarang paper, the *Indische Vaderland* of the 30th December, the Netherlander from Deli who has been inquiring into the suitability of North Borneo for tobacco-growing is Mr. L. F. Saunders, who had been commissioned by the British North Borneo Company to ascertain whether the tobacco grown by the natives there would answer, when planted and prepared for the European market. Mr. Saunders thus sets forth the result of his researches in the coast district:—

"I was rejoiced to find that the genuine tobacco plant, and not the inferior wild variety, grew very luxuriantly in Sabah, and that the product was of such a nature that even under the careless management of the natives the leaves reach each a length of one foot. The seeds and hence also the tobacco are indigenous, and may be considered as belonging to the 'Palembang' variety. The leaf terminates where the midrib commences, the latter being bare with the exception of a few small hairs. In shape the leaf is very broad at the lower end, and is only ovally rounded off at the point, while both leaf and fibres leave nothing to be desired in fineness. The almost total freedom from holes, notwithstanding the notorious indolence of the growers, furnishes proof of the fortunate absence of worms, locusts, and other vermin. During the growth of the tobacco plants, rain showers usually fall at night, whereby spotting and rust are prevented. So far as I can judge from a single season's samples, the ash is pure white, and the smell is not only unobjectionable, which alone would be enough for tobacco intended only for covering, but even pleasant so that the smaller leaves available at each crop and used as filling will be more suitable for that purpose than many Java kinds. The seasons and rainfall are favourable. The rainy season begins in the middle of August, so that the beginning of April is the fittest time for planting. In configuration the country traversed consists of steep hills with small tops, while plains are either altogether absent or almost so, what few there are being only in the valleys between the hills. After clearing the ground the natives plant paddy on the slopes of these hills, and afterwards tobacco in small quantities, but only for their own consumption. I found tobacco growing luxuriantly at the height of 3,000 feet, showing all the good qualities enumerated above. It struck me that the elevation of the land exercises a favourable influence on the fineness of the leaf." Mr. Saunders describes the formation of the soil in Sabah as very suitable for tobacco cultivation, the chief difficulty to be overcome being scarcity of labour, while land transport will be found indispensable, from the currents in the numerous rivers and streams being too strong and dangerous for the conveyance of produce and materials. Towards the conclusion of his trip, he examined in the valley of Rachak the most extensive tobacco plantation he had yet seen, its area being half an acre, and collected there many large green leaves for the purpose of drying them by way of experiment. Mr. Saunders, though admitting that the quality of tobacco can only be ascertained after being thoroughly fermented and cured, comes to the following conclusion:—"Without arousing too great expectations, it may safely be assumed, considering the favourable ascertained characteristics of variety, size, fineness of leaf, smell and ash (unfermented), that at a height of 2,000 feet on land not too hilly, and with a European mode of cultivation, tobacco crops of superior quality may probably be secured."

ZULULAND AND CETEWAYO.

"I know what it is," he answered; "this honey is made from euphorbia flowers, which are very poisonous." This explanation made me feel exceedingly uncomfortable; but I elicited from him that there was not much danger, as the 'maass' taken with it would neutralise the effect of the poison. Directly he mentioned poison I dived into the packs, and pulled out a bottle of ENO'S FRUIT SALT, and emptying a quantity into two pannikins, filled them up with water, and several times repeating the dose, in a few hours we were considerably better."—*"Zululand and Cetewayo," (p. 139), by Captain W. R. Ludlow, 1st Batt. R. V. Royal Warwickshire Regiment.*

"What on earth shall I take to Zululand?" asked my friend Jim Law one day at Aldershot, when he had just received orders for South Africa, to start at forty-eight hours' notice. I replied, "If you take my advice—and it's that of an old traveller—you'll not budge without a few bottles of ENO, even if you leave half your kit behind. I never am without these Salts, and, please the pigs, never intend to be." On his return I inquired, "Well, how about ENO'S FRUIT SALT?" "My dear fellow, it was the best advice you ever gave; they saved me many an illness; and when I left Tugela, I sold the remaining bottles for ten times the original price!"—*Lieut.-Col.*

JEOPARDY OF LIFE. THE GREAT DANGER OF DELAY.

You can change the trickling stream, but not the raging torrent.

WHAT EVERYBODY SHOULD READ.—How important it is to every individual to have at hand some simple, effective, and palatable remedy, such as ENO'S FRUIT SALT, to check disease at the outset! For this is the time. With very little trouble you can change the course of the trickling mountain stream, but not the rolling river. It will defy all your tiny efforts. I feel I cannot sufficiently impress this important information upon all Householders, or Ship Captains, or Europeans generally, who are visiting or residing in any hot or foreign climate. Whenever a change is contemplated, likely to disturb the condition of health, let ENO'S FRUIT SALT be your companion; for, under any circumstances, its use is beneficial and never can do harm. When you feel out of sorts, yet unable to say why, frequently without any warning you are suddenly seized with lassitude, disinclination for bodily or mental exertion, loss of appetite, sickness, pain in the forehead, dull aching of back and limbs, coldness of the surface, and often shivering, &c., &c.; then your whole body is out of order, the spirit of danger has been kindled, but you do not know where it may end: it is a real necessity to have a simple remedy at hand that will answer the very best end, with a positive assurance of doing good in every case and in no case any harm. The pilot can so steer and direct as to bring the ship into safety, but he cannot quell the raging storm. The common idea when not feeling well is, "I will wait and see, perhaps I shall be better to-morrow;" whereas, had a supply of ENO'S FRUIT SALT been at hand, and use made of it at the onset, all calamitous results might have been avoided. What dashes to the earth so many hopes, breaks so many sweet alliances, blasts so many auspicious enterprises, as untimely death?

ENO'S FRUIT SALT.—After suffering for nearly two and a half years from severe headache and disordered stomach, and after trying almost everything and expending much money without finding any benefit, I was recommended by a friend to try ENO'S FRUIT SALT, and before I had finished one bottle I found it doing me a great deal of good, and now I am restored to my usual health; and others I know that have tried it have not enjoyed such good health for years.—Yours most truly, ROBT. HENDERSON, Post Office, Barrasford.

SUCCESS IN LIFE.—A new invention is brought before the public, and commands success. A score of abominable imitations are immediately introduced by the unscrupulous who, in copying the original closely enough to deceive the public, and yet not so exactly as to infringe upon legal rights, exercise an ingenuity that, employed in an original channel, could not fail to secure reputation and profit.—ADAM.

CAUTION.—Legal rights are protected in every civilised country. Examine each Bottle, and see the capsule is marked "ENO'S FRUIT SALT." Without it you have been imposed on by worthless imitations. Sold by all Chemists, price 2s. 9d. and 4s. 6d.

DIRECTIONS IN SIXTEEN LANGUAGES HOW TO PREVENT DISEASE.

Prepared only at ENO'S FRUIT SALT WORKS, HATHAM, LONDON, S.E., by J. C. ENO'S Patent.

GRATEFUL—COMFORTING.

EPPS'S COCOA.

BREAKFAST.

"BY a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately-flavoured beverage which may save us many heavy doctor's bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—See article in the *Civil Service Gazette*.

Made simply with boiling water or milk.

Sold only in packets, labelled—

JAMES EPPS & CO.,

THE GREAT REMEDY FOR PRICKLY HEAT, INDIGESTION, HEADACHE, BILIOUSNESS, AND FEVERS.

LAMPLOUGH'S PYRETIC SALINE,

The testimony of medical gentlemen has been unqualified in praise of
 It is a purgative element most essential for the restoration and maintenance of health with perfect vigour of body and mind.
 It is Refreshing and Tasteless; forming a most invigorating, Vitalising, and Refreshing Beverage.
 Gives instant relief in HEADACHE, BILIOUSNESS, CONSTIPATION, INDIGESTION, LASSITUDE, BRUISTURN, and FEVERISH COLIC; prevents and quickly cures the worst form of FEVER, MALARIA, JUNGLE, and other FEVERS, and all other ailments of the blood.
 Dr. FROST: "Unquestioned source of immense benefit to mankind."
 Dr. MORLEY: "It is the best blood purifier and the best saline constituent."
GOVERNMENT OFFICIALS AND PLANTERS caring for the welfare of their employes should note its value as a specific in Fever cases.
 Dr. J. W. DOWNS: "I used it in the treatment of forty-two cases of Yellow Fever, and in every case I never lost a single case."
 Dr. W. H. HARRIS: "Since its introduction the Fatal West India Fevers are deprived of their terror."
 H. HARRIS, REPRESENTATIVE of the GOVERNOR of SIERRA LEONE, in a letter of request for an additional supply of the Pyretic Saline, states: "It is of great value, and I shall rejoice to hear it is in the houses of all Europeans visiting the tropics."
 To be obtained of any Chemist or Drug Store, in Patent Glass-stoppered Bottles, 2s. 6d., 4s. 6d., 11s., and 21s. each.
 Please note in connection with the recently observed effects of the use of Oils and other preparations of Magnesia that **LAMPLOUGH'S PYRETIC SALINE** is warranted not to contain any substance which would cause calculus or other earthy deposits.

H. LAMPLOUGH, 113, HOLBORN HILL, LONDON, E.C.

NOTICE

TO MANUFACTURERS,

AND

OTHER USERS OF POWER IN BULK.

WATER POWER, varying from 100 to 1,000 H.P., is available at 38 sites on the Bari Doab and Western Jumna Canals in the Punjab.

The tracts in which the Water Power is situated are—

(a) Between the rivers Beas and Pavi, to the north of the Soinda, Punjab and Delhi Railway, 26 sites, close to the Umritsur and Pathankote Railway now under construction.

(b) To the west of, and about 16 miles from the river Jumna, 12 sites, on a navigable canal running from Karnal to Delhi, and within easy distance of the Grand Trunk Road.

Lease will be granted for 20 years, on the following approximate rates per H.P. per annum:—

| | | | |
|-----------------------|-----|-----|---------|
| For the first 3 years | ... | ... | Rs. NIL |
| " " second 5 | " | " | " 60 |
| " " third 6 | " | " | " 100 |
| " " fourth 6 | " | " | " 150 |

Full particulars can be obtained from the Office of the Joint-Secretary to Government, Punjab, Irrigation Branch, Lahore, and information, regarding the Water Power available at the various sites and their local advantages, can be obtained from the office of the Superintending Engineer, Bari Doab Canal, Umritsur, and Superintending Engineer, Western Jumna Canal, Delhi.

By order,

Manufacturers of and Agents for Sale of

JEBEN'S

Patent Swift and Sure Transplanting Tools.

GOODALL'S Household Specialities.

A Single Trial solicited from those who have not yet tried these Splendid Preparations.

YORKSHIRE RELISH.

The Most Delicious Sauce in the World.

This cheap and excellent Sauce makes the plainest viands palatable, and the daintiest dishes more delicious. With Chops, Steaks, Fish, &c., it is incomparable. In bottles, at 6d., 1s., and 2s. each.

GOODALL'S BAKING POWDER.

The Best in the World.

Makes delicious pudding without eggs, pastry without butter, and beautiful light bread without yeast. In 1d. packets, 6d., 1s., 2s., and 5s. tins.

GOODALL'S QUININE WINE.

The Best and most Agreeable Tonic yet introduced.

The best remedy known for Indigestion, Loss of Appetite, General Debility, &c. Restores delicate individuals to health. At 1s. 1d. and 2s. 3d. each bottle.

GOODALL'S CUSTARD POWDER.

For making Delicious Custards without Eggs, in less time and at half the price.

The Proprietors can recommend it to Housekeepers generally as a useful agent in the preparation of a good custard. Give it a TRIAL. Sold in boxes, 6d. and 1s. each.

GOODALL'S GINGER BEER POWDER

Makes Three Gallons of the Best Ginger Beer in the World for Threepence.

The most valuable preparation for the production of a delicious and invigorating beverage. It is easily made, and is by far the cheapest and best Ginger Beer ever offered to the public. Sold in packets, 3d. and 6d. each.

GOODALL'S EGG POWDER.

Its action in Cakes, Puddings, &c., &c., resembles that of the egg in every particular. One penny packet will go as far as four eggs and one sixpenny tin as far as twenty-eight. Sold everywhere, in 1d. packets, 6d. and 1s. tins.

GOODALL'S BLANCMANGE POWDER

Makes delicious Blancmange in a few minutes. In boxes at 6d. and 1s. each.

All the above-named Preparations may be had of all Grocers, Chemists, Patent Medicine Dealers, and Oilmen.

Proprietors: GOODALL, BACKHOUSE & CO, Leeds, England.

FREEMAN'S SYRUP OF PHOSPHORUS.

Nature's Great Brain and Nerve Tonic and the most wonderful Blood Purifier. The highest Medical Authorities say that it is the only Cure for Wasting Diseases, Mental Depression, Loss of Energy, and Stomach Complaints.

It is pleasant to the taste, and might be taken by the most delicately constituted. In the most enfeebled it builds up a NEW AND HEALTHY CONSTITUTION. One dose of this Remedy is equal to Twenty Doses of Cod-Liver Oil.

Thousands have been snatched from the brink of the grave by the timely use of FREEMAN'S SYRUP OF PHOSPHORUS. May be had of all Chemists and Patent Medicine Vendors, in bottles at 2s. 9d., 4s. 6d., 11s., and 22s.

IN EVERY PART OF THE WORLD,

INCLUDING—

The Proprietors, *Indian Agriculturist*, Chowringhee-road, Calcutta; the Great Eastern Hotel, Company, Limited, Calcutta; Messrs. Wilson, Mackenzie & Co., 18, Old Court House-street, and 1, Mangoe-lane, Calcutta. Orders received by Messrs. King, Hamilton & Co., Calcutta.

NOTICE.

In ordering through London Shippers, purchasers should be particular to stipulate for SUTTON'S SEEDS.

TESTIMONIAL.

From S. Jennings, Esq., late Vice-President of the Agri-Horti Society of India.

"With reference to your mode of packing seeds for export, I must say how much I was gratified with the system you were so good as to show me. During the whole of my long Indian experience, it was my constant regret that English packed seeds were almost invariably lower in germinating power than the American. After seeing the elaborate precautions you take in executing such orders as that of the Agri-Horti Society of India, I am by no means surprised to hear that you have been gratified by the receipt of so much testimony from the tropics as to the condition of your Seeds upon arrival."

WHITEFRIAR'S-STREET, LONDON,
HYDRAULIC ENGINEERS AND MANUFACTURERS OF
PUMPING MACHINERY OF EVERY DESCRIPTION
FOR STEAM, WATER, WIND, CATTLE, AND MANUAL POWER.

Hydraulic and Screw Presses, Oil Mill Machinery, Hydraulic Lifts, &c.

SOLE MAKERS FOR GREAT BRITAIN OF

BLAKE'S PATENT DIRECT-ACTING STEAM-PUMP,—MORE THAN 10,000 IN USE

THE FOLLOWING ARE SOME OF THE PROMINENT ADVANTAGES OF THE BLAKE PUMP—

It will start at any point of stroke.

It has no dead point.

It works fast or slow with the same certainty of action.

It is economical. Has a lead on the Slide Valve.

It is compact and durable.

Hand Power Lever Detached.

It is interchangeable in all its working parts.

It will deliver more water than any other Pump.

It is made of best materials in the most workman-like manner.

Can be worked at 200 strokes per hour, or 20 strokes per minute.

Deep-well Pumps, for Horse or Bullock Power.

Vertical Combined Steam Engine, Boiler, and Deep-well Pumps.

BLAKE'S PATENT Direct-Acting Steam Pump and Boiler Feeder.

COMPLETE OIL MILL. Oil Mills, for Steam or Cattle Power.

Double-barrel Condensers' Pumps, for Hand or Steam Power.

Double-barrel Fire Engines, for Mansions, Factories, &c.

Deep-well Pump for Hand Power.

Improved Steam Boring Apparatus, also

Boring Tools of every description, for Artesian Wells, testings for Minerals, Foundations, &c.

Double-barrel Force Pump in Frame.

Fire Engines, for Towns, Railway Stations, &c.

Force Pumps on Barrow.

Wrought-iron Portable Pumps.

Patent Centrifugal Pumps, for Condensers and Irrigation Work.

Cast-iron House or Garden Pump.

Portable Irrigation, for Horse or Hand Power.

BLAKE'S PATENT DIRECT-ACTING STEAM PUMP AND VERTICAL BOILER
FOR IRRIGATION PURPOSES,
FILLING TANKS, WATER-SUPPLY TO PLANTATIONS, SMALL TOWNS OR VILLAGES.

Whitefriar's Ironworks, Whitefriar's-street, Fleet-street, London.

THE UNIVERSITY OF CHICAGO

23

[No. 4]

SPECIALLY DESIGNED FOR AND PATENTED IN INDIA AND ABROAD

— 22 —

1802.
Diploma.

Cincinnati, June 1940

Including 3,577 feet of main Driving Belts, of widths ranging from 18 in. to 60 in., are working in over 5,000 Mills and Works in Europe and America.

New Zealand, 1882.

**Best Double Layer 8 in. Baling
Gandy's 6 in. x 8-ply Cotton**

It is the best belt ever made for all purposes. Much Cheaper and Stronger than Leather. Thoroughly Waterproof, and not affected by temperature, clings well to the pulleys, runs true, and can be made any length without joints.

This Series of Belting (see engraving) was supplied in One Order to Messrs. John Crossley and Sons, Halifax, May 1, 1880, and continues to give entire satisfaction.

GANDY'S Patent American Cotton Belting can claim a superiority over leather belts in every particular; its cost being about half that of leather, while its strength and gripping power is about double that of the best leather. As shown by repeated tests taken by Kirkaldy & Co., of London. These tests are given above, to which special attention is drawn. These "Gandy" belts are made of any width up to 72 inches, and any length up to 340 feet with joint, thus obviating the necessity of having two belts on the same pulley, a system of driving which is never satisfactory, as it is impossible to have belts of exactly the same tension; hence one or the other is always causing a stoppage. These stoppages are avoided by using Gandy's Patent Belts in one width. These Gandy Belts are made of the finest American Cotton Duck, specially prepared at Baltimore for the purpose, and then put together and finished by "Gandy's" special special Machinery, and process to prevent stretching and render them impervious to atmospheric influence. The numerous advantages such as these, the universal adoption of Gandy's Belts can only be a question of time.

A SUBSTANTIAL GUARANTEE GIVEN WITH EVERY MAIN DRIVING BELT

HERA

HEALTH, STRENGTH, AND ENERGY.

DR. LALOR'S PHOSPHODYNE.

(Trade Mark—Phosphodyne.)

TWENTY YEARS' PUBLIC TEST, AND THOUSANDS OF TESTIMONIALS FROM

ALL PARTS OF THE WORLD ESTABLISH

PHOSPHODYNE

as the only Safe, Reliable, and Never-failing Phosphoric Remedy for Over-worked Brain, Sleeplessness, Harassing Dreams, Worry, Anxiety, Excitement, Epilepsy, Business Pressure, Wasting Diseases, Nervous Prostration, Stomach and Liver Complaints, Impoverished Blood, Premature Decay, and all morbid conditions of the system dependent upon the deficiency of the Vital Forces.

DR. LALOR'S PHOSPHODYNE PURIFIES AND

Enriches the Blood, Clears the Skin, thoroughly Invigorates the Brain, Nerves and Muscles, Re-energises the Failing Functions of Life by supplying the Phosphoric element which has been wasted, and thus imparts Energy and Fresh Vitality to the Exhausted Nervo-Electric Force, and rapidly Cures every form of Nervous Debility, Paralysis, Kidney, Nervous, Mind, and Heart Diseases, from whatever cause.

This elegant Phosphatic combination, the Wonder of Modern Chemistry, is pronounced by the most eminent members of the Medical Profession to be unequalled for its power in replenishing and elaborating the Vitality of the Body; by its supplying all the essential and vitalising constituents of the Blood, Brain, and Nerve Substances; and for developing all the Powers and Functions of the System to the highest degree; by its being agreeable to the palate, and innocent in its action. While retaining its wonderful properties, it acts as a Specific, surpassing all the known PHOSPHATIC AGENTS of the PRESENT AGE, for the SPEEDY and PERMANENT CURE of the above disease.

DR. LALOR'S PHOSPHODYNE is sold in Bottles at 4s. 6d. and 11s. by all Export, Wholesale, and Retail Medicine Vendors throughout the World.

IMPORTANT NOTICE.—NONE IS GENUINE UNLESS the name, Dr. Lalor's Phosphodyne, London, England, is blown in the Glass of each Bottle, and every Bottle bears the British Government Stamp, with the words DR. LALOR'S PHOSPHODYNE, London, England, engraved thereon by Order of her Majesty's Honourable Commissioners; IF NOT, IT IS A FORGEY, AND YOU HAVE BEEN IMPOSED UPON BY A WORTHLESS IMITATION.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bighah in particular varies so much in the different provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

THE SILK INDUSTRY.

TO THE EDITOR.

SIR,—In your esteemed columns long letters have been appearing regarding the Bengal silk. Your correspondents generally bemoan the fate of Bengal silk as an industry that is dying off, abuse the spinner or *katanies*, and try to prove by various and many arguments why the silk in Bengal will never be again what it once was, and what ought to be done to resuscitate it, &c.

I have had a good many years of experience of silk filatures, both on the Rajshaye side of the Ganges, and on the Moorshedabad side too. I have also seen something of it in Beerbhoom and elsewhere, and even now I hear one way and another a good deal about silk filatures.

My experience goes to show me that, so far from the silk industry dying out, it is very flourishing; but of course as the Europeans have done their best, and are doing their utmost, to make dealings with them disagreeable to the dealers in cocoons why, they are losing the business, and as the local consumption of silk has increased a hundred-fold, and cannot be traced by the European producer or the Government, it is lost sight of, and a "hue and cry" is raised as to the falling off of the silk industry.

One of your correspondents writes as if he was training for Holy Orders, and dogmatically lays down the law by stating that a small filature contains fifty men and fifty women, and a large one five times as many of each sex. He does not know that, across the Ganges, on the Rajshaye side, where probably 30,000 to 60,000 hands reel silk every day, during the season, there are not among them 50 women *katanies*. I knew a charge of 900 basins in which there was not one female *katanie*, and most of the men were married men with families, and many of them kept their women as *purdanushceens*—i.e., their women were not permitted to be seen out of their homesteads. How is it that the curse complained of on the Moorshedabad side, where single men and women carry on much of the work, falls on the respectable lot too?

Again, one man writes about "rack-renting" that, too, is absurd. If the mulberry fields were to pay three times the rent they are now charged with, they would still leave a handsome margin to the cultivator.

Lastly, comes a man who wants to run off with the cocoon eggs to the hills, and abuses the Bengali *katanie* as being incapable and lazy, &c.

To this man I say there is no more patient worker than a Bengali, and value for value, the Bengali workman will beat any workman except the Chinaman.

Then, as to cocoons. If your correspondents can afford to do prodigies, then of course they can call out *nous avons changé tout cela*, but as they cannot, I suppose things must remain as at present.

To any one who has been behind the scenes, and to any one who has studied the subject, the reason for the decline in the quality of Bengal raw silk, as sent to the home markets, is very plain indeed.

The cocoons taken all in all are much as they were formerly. There are good batches and bad batches, and the best of silk and the worst of silk will be the produce of them respectively. The *katanies* are fit to spin any class of silk, and would, if at liberty, spin silk that could not be beaten or be found fault with. The machinery and filatures are better than they were in former years, and easier worked. And the whole secret lies in the fact of managers wishing to make impossible quantities of good silk at impossible rates, and to a pernicious system of management that will only end when the older hands have brought ruin on the

business, have been compelled by that ruin to clear out, and new blood and a more reasonable and judicious routine of business has come in.

Why, Mr. Editor, when I tell you that in most of the filatures the scale of salary paid to katanies thirty years ago is still persisted in, you will easily understand how it is that the business is being ruined. Food, living, the value of money, and in fact almost every item of domestic economy, has undergone a change in Bengal, but the katanies' salaries, wherever the "autodidivians" have the power to carry it out with the strong hand, have remained in *status quo*. Rice may sell at one rupee per maund, or five rupees per maund it makes no difference. Five rupees and four rupees they got respectively year out of mind, and that they must get, if not, how is silk to pay?

Again, as regards quality of silk. I have stated that the cocoons, when sorted and worked fairly, will yield silk of similar quality, in fact, as good silk as can be desired may be produced; but the cocoons are not sorted to make special classes of silk, and, as a rule, the spinners are bound to make only such a class of silk as pays, and they do it. Doubtless the managers want, and would like to have, the best of silk, but it does not pay to have the best of silk, and they take, with all sorts of make-believe of dissatisfaction, what they can get, and do their best after they have got it, to pin their faith to it, and pass it off as the best in quality that can be reeled.

You will say that my statement smacks of a paradox. Well, so it does, but nevertheless, it is true. The process by which the arrangement comes about requires explanation. To begin with every filature, as a rule, has a head native—the gomashta, who is responsible for all the money sent to the filature, the cocoons bought at or by the filature, the quantity and quality of silk made, and the losses incurred on cocoons with which the silk is made. There is an assistant, too, in each filature, or in charge of two, three, or more filatures, but he is a sort of "nonentity" kept to look after the general working, to draw commission on all the silk made, and to keep the natives in some sort of check. He is expected to see, too, that good silk is reeled. As the season opens, the money comes in from headquarters for the purchase of cocoons, and with it an order or hint up to which each seer of silk will be paid for at headquarters exclusive of reeling expenses. Thus, if an order of Rs. 10 per seer is given, and a maund of cocoon yield three seers by estimation of silk, then the gomashta can pay Rs. 30 for that maund of cocoons.

Now, if the gomashta buys those cocoons for Rs. 30, and they yield only two seers of silk, he is Rs. 10 to the bad silk. There is the secret and actual reason why bad silk is made. The gomashta, being responsible, takes very good care that he obtains all the produce he can from the cocoons, and the spinners are told to work accordingly.

Here I must digress to point out that each cocoon contains as a covering a certain quantity of coarse, loosely put together, silk. This must be cleared off if a clean fibre is wanted. The clearing this flimsy covering represents so much loss in produce of good raw silk, and the reeling off of some of it with the clean fibre is so much gain of produce, the gomashta elects for the latter. Well, where it is understood that the gomashta is bound in his own interests to obtain produce, it is very simple to follow up the reasoning, and the result or conclusion comes to is that the katanies as a rule are not permitted to work with the view of making the best silk possible, and therefore, not being free agents, they cannot be blamed for turning out bad silk.

Having shown what is the actual root and origin of bad silk, I will proceed to add that the system of checks at head-quarters to test the quality of silk is simply bad. The natives who carry out the testing are fearfully corrupt. I know a large concern—in fact, one of the largest concerns in Bengal—in which it is usual for the gomashtas to send money with each despatch or lot of silk, and provided a good amount accompanies the silk, no matter what the quality of the silk is, it passes as first class. The managers profess to know nothing of this, and this evil, being the outlet to work off the silk, resulting from produce, damages the whole business.

It may be urged that I am exaggerating, but such is not the case. I have seen silk not fit to be sent to market passed, and on the other hand, I have seen first-class silk reported on as bad, and all the native hands fined for it. The gomashtas naturally say what is the good of using produce and making good silk when one has to bribe to see it passed, just the same as is done for the bad silks.

It is easy to deduce from this that so long as filatures are managed under a system that centres all loss on the gomashta, no first class silk can be expected as a rule.

Of course there are exceptions to every rule, and the exception is this—when very good batches of cocoons happen to be bought, they seldom turn out bad silk off them. But in these cases too the assistant, unless he is very smart, is powerless, because the good cocoons are often mixed with the bad cocoons.

It will be asked that if it is in the interest of the gomashta to make bad silk, and all the gomashtas make bad silk, how is it that any good silk is made? Why, it is a continual "pull-devil-pull-baker" sort of a game. Managers and assistants now and then punish the men, and create a reign of terror for a few days, when a little good silk is made, then it gradually falls back to the old standard, and bad silk continues to be reeled.

To sum up. The demand for local consumption is now very great. In the villages, formerly only the rich men wore silken apparel; now coolies do so. The demand stimulates production, coarse threads are reeled for the weaver, the yield from cocoons of such thread is greater than as fine thread, and thus the natives carry off cocoons that to the European is prohibitive; the European outturn falls short, no one takes the trouble to probe the matter, and a general outcry is made of the silk industry dying off.

It would be very easy to follow up what I have written above, and to show how it is that the Europeans are gradually but most perseveringly putting an end to the carrying on of silk business so far as concerns their filatures. In a few years more they will have about a fifth of their filatures only at work, and those also will work about 4 to 6 months in the year, but I have no time to write more to-day, so will leave the matter for my next.

SILKWORM.

THE USES OF CHEMICAL ANALYSIS IN A PRACTICAL POINT OF VIEW.

TO THE EDITOR.

SIR,—In bygone ages when the science of chemistry was in its infant stage, analyses of soil or those of any other thing, in the material world, in civilized countries, and for practical purposes, were a mere something for the gratification of enquiring minds; because the then discoveries, in the science, were so few that the results *perforce* became very unsatisfactory, accurate finding out being then almost impossible. Again, in those days very few people had a knowledge of chemistry, and that knowledge was so very limited that its use, in practice, was a matter of question; hence agriculture and other cultivations, the arts and manufactures, medicine, house and other buildings, and various other things too numerous to detail here, had to be managed without the help of chemistry; and of course in very crude or imperfect, and unsatisfactory fashions. The time I here allude to embraces the primitive and dark ages. As, however, time rolled on and discoveries were made, things assumed different aspects; so that in the present time chemistry, in civilized countries, is considered absolutely necessary, because chemical manipulations have, practically, been found to be productive of the happiest results in multifarious ways. Chemistry, it should be noted, is a purely *experimental demonstrative science*. To elucidate the subject, I must say that the chemical constituents of (1) the solid food we eat; (2) the liquid food, such as milk, wines, spirits, beer, porter, various other beverages, and the water we drink; (3) the medicines, whether externally or internally, we use; (4) the ores we dig out of the ground; (5) the salts and earthy matters we extensively use in the arts and manufactures, also as food ingredients; (6) *materials* of dyeing; (7) the compounds of metals and minerals we use in the arts and manufactures; (8) the clay, sand, and stones we use as building materials for conversion into bricks, lime, and mortar and in pottery; (9) the soils in which plants grow; (10) the atmospheric air, manures, and irrigation waters which serve, in addition to the soil, as food for plants; (11) and lastly, though not the least, the plants themselves—are all required to be known, and known in most cases thoroughly, before we can decide their adaptability for special or general purposes, and fix their commercial or intrinsic and revenue value accordingly. What I have advanced, no one having his intellect sound, knowledge and education perfect

requiring much more can less expensively be grown in India than in those countries. But the foregoing famous investigation by these distinguished and very high authoritative doctors, and other things mentioned above could not have been made without the help of chemical analyses, therefore its great practical use as respects soils of all kinds and depths, and for all manner of plant cultivations.

10. Chemical analysis of atmospheric air, the most tedious and time-absorbing in the whole range of analytical chemistry, is of a character which might be likened to the Director in whose hands are the destinies of the present and future races of *organic nature* of our planetary orb, earth. I will presently explain in which way air analysis assumes this most important character.

The component elements of the atmospheric air, it is well known, consists of *nitrogen, oxygen, hydrogen and carbonic acid* principally; and *chlorine, phosphoric acid, and sulphuric acid* in, comparatively speaking, insignificant quantities. These substances exist in the shape of gases and blended in different proportions or *volumes*; hence to use the words of Boussingault and Dumas the atmospheric air is a 'true mixture.' The properties of all these elements are also fully known to every one knowing anything of science. In organic nature an equilibrium, termed by the distinguished chemists and physiologists whose names have been cited, 'balance,' is maintained. This balance is the source of life to plants and animals of all kinds and in all places, dry land and water; but it cannot be always maintained, its breakage, in the physical world, being already threatened by the very rapid increase of human beings and animals of all kinds subserving the purposes of man, besides these in a wild state not yet extirpated, also plants of numerous kinds to supply food and other wants of man and animals subject to man. All these are constantly robbing the air of its moderating element—*nitrogen*, for such is the real character of this element, and since the processes of *evolution* and *involution* are disengaging only a very small fraction of what nitrogen element they are storing in their structures, the *balance of organic nature* cannot hold out long, but, sooner or later, must break up by the paucity of nitrogen in the air. The very moment this takes place, the all-powerful life-maintaining and at the same time life-destroying *oxygen* gas will break asunder its present mildness, become violent and burst out in flames. When this takes place universal lightnings (violent electric sparks), thunders of the most virulent character, cyclones, probably at the beginning hail and rain also, and earthquakes, on account of nature following the laws of gravitation discovered by Sir Isaac Newton, and cohesion, will take place; and gradually, by immense physical changes which will then take place, the planet earth will be enveloped by one uninterrupted mass of flames, whereby the whole animated nature including plants, will be burnt up, not a single human being will be found living. All the waters on the earth, such as seas, oceans, lakes, rivers and wells, will boil and partially or wholly be dissipated like water in a cauldron does when placed on fire, consequently fishes and other animals living in water will perish, and then the bible prophecies quoted below will be fulfilled to the very letter.

'But the day of the Lord will come as a thief in the night, in the which the heavens shall pass away with a great noise, and the elements shall melt with fervent heat, the earth also and the works that are therein shall be turned up.' II Pet. III, 10.

'And great earthquakes shall be in divers places, and famines and pestilences: and fearful sights and great signs shall there be from heaven.'—St. Luke XXXI, 11.

'Immediately after the tribulation of those days shall the sun be darkened, and the moon shall not give her light, and the stars shall fall from heaven, and the powers of heaven shall be shaken.'—Math. XXIV, 29.

Other passages in the New and Old Testaments might also be referred, which exactly tally with science and the Scriptures, and it do not vary to the very letter.

The use of chemical analysis of air consists in the data it can furnish from time to time, regarding the proportion of the gases in the atmospheric air on which to base scientific and

political measures for, at least, prolonging the inevitable prophesied destruction.

The manures and irrigation waters, because supplying plant-food ingredients, also require to be analysed.

II.—The chemical analyses of plants are very important, both for gaining the necessary knowledge for growing them, and for what uses they are adapted.

The inference of the whole said above at once brings home to the minds of the most superfluous thinker the great importance of chemical analysis in a practical point of view.

Some people advance that various results are obtained in analysis. To them I say, efficient analysis always does its work admirably and can trace down to *one millionth part of a grain*, which *datum* certainly is quite enough for all practical purposes. It is true, various analytical methods exist giving various results; in reality, however, there is but one method for such analysis, and the sooner this method, which must be the most approved one, is agreed upon, by chemists, the better for progress. The most approved method consisting in the most approved way adopted, chemicals and apparatus used in the particular chemical manipulation (analysis). To my mind all chemists and chemical societies in all parts of the world, ought to arrive at this all-important decision, the sooner the better.

O. L. BRYCE.

Bahraich, March 12, 1883.

The Indian Agriculturist.

CALCUTTA, APRIL 2, 1883.

FUEL AND FODDER RESERVES.

IN the supplement to the *Gazette of India* for the 10th March, there is a very important resolution on the conservation of grazing lands and wooded tracts, especially in the provinces of the Punjab, the North-West, and the Central Provinces, including the Berars, which we reproduce elsewhere, and to which we desire to draw the attention of our readers. It is perfectly clear to those who have studied the agricultural condition of India, that some such measure as that proposed in the resolution is becoming year by year more imperative. The rapid increase of population following from the peaceful rule of England which has reduced to a minimum loss of life from war, pestilence and famine—those natural checks to the growth of population, coupled with the hitherto all but insurmountable repugnance on the part of the bulk of the Indian peasantry to any scheme of emigration on a large scale—make it imperative that jungle land should be cleared for grazing purposes and the latter in turn utilized for arable land in larger and still larger areas year by year. The pressure of the population on certain areas in India renders the struggle for existence more and more keen, and in this struggle, it is very evident that ignorance, want of thrift and foresight, as well as poverty and the hereditary apathy of the Indian peasant, have worked mischief to the land and its power of producing fodder, fuel, and food, which, though not irreparable, has in Upper India and elsewhere produced conditions which render it impossible, should a single monsoon fail, to keep alive the plough cattle, and which even imperil the lives of the cultivators. We do not believe that it is possible with such a peasantry as that of India, or indeed any peasantry mainly dependant for existence on the safe gathering of almost a single crop, to do more with one generation, at least, than render their lot a little less hard. Habits, methods and idiosyncracies crystallised and hardened beyond any hope of remoulding, as well as tribal and race characteristics ingrained in the web and woof of the people's lives, render change and innovation all but impossible with those who have reached middle life, while even with the rising generation a fresh set of conditions and surroundings, broader ideas and newer methods are but things of slow growth.

Nevertheless, as we have said, some little may be done to render their lot less hard, to stave off impending calamities, and to avert evils which ignorance, poverty, and thoughtlessness have already produced and are producing; and it is in this direction that the Agricultural Department will find, in our estimation, the widest and the truest scope for its usefulness. The resolution above noted proposes to maintain throughout the plains of Upper India a supply of wood for fuel and domestic purposes, as well as of fodder for cattle in times of scarcity, or rather we should say, fodder resources are the object chiefly aimed at, in the securing of which a supply of fuel will also be obtained. The plan proposed is that the Forest Department should be consulted regarding the best means of bringing waste lands into a condition suitable for the purposes aimed at; that certain areas should be enclosed to prevent the destructive grazing of goats and cattle, and supply fuel and food in times of need, and in this way to restore, and if possible increase, the usefulness of land which is fast decreasing, or has already been practically lost. The advice and co-operation of Local Governments is asked regarding the form in which system and continuity can be most advantageously established. The whole details of the practical working of the scheme are, it will thus be seen, wisely left untouched until such time as the various officers who may be supposed to have an intimate knowledge of the localities, and the various matters implied in such an undertaking, have recorded their opinions and experience. At its present stage, then, all we desire to do is to commend the wisdom of the proposal, and to hope that the department from which it emanated will be able in a few years to say that in the districts where fuel and fodder reserves have been established loss of cattle to any great extent is rare, that land previously waste and comparatively useless, has been covered with forest and grazing grounds, and that the peasantry of these districts is thriftier, healthier, and more prosperous than those in less favoured districts.

IRRIGATION IN BENGAL.

THE Revenue Report of the Public Works Department, Irrigation Branch, Bengal, for the year 1881-82, has been published. It shows that the capital invested in irrigation works in Bengal (direct charges), up to the end of the year under notice, amounted to Rs. 5,48,10,043. This was divided as follows:—

| | Rs. |
|-------------------------|-------------|
| Productive Public Works | 3,24,57,080 |
| Imperial Ordinary Works | 8,30,624 |
| Provincial Works | 13,21,439 |

The results of the operations during the year show a deficit of Rs. 19,22,213 (this includes interest and all indirect charges), against Rs. 23,06,111 in 1880-81, or excluding interest, but including all indirect charges, a profit of Rs. 1,52,975, against a loss of Rs. 31,353 in the previous year. This comparatively favourable result is partially due to the rate of interest payable to the Supreme Government on works executed from loan funds having been reduced from $4\frac{1}{2}$ to 4 per cent, but it is also largely owing to increased receipts from the Sone canals. The net receipts for the year from the Western Main series of the Sone project—the capital expenditure on which has been Rs. 1,59,92,879—were Rs. 2,76,564, against interest charges amounting to Rs. 6,04,022; so that on parts of the irrigation works, the returns have begun to bear a very appreciable ratio to the burden they caused to the provincial finances.

The collections in Midnapore and Orissa were not satisfactory, mainly owing to the low prices for rice, which continued to prevail. It is stated that since the close of the year under review considerable progress has been made in realizing the arrears in Orissa, but in Midnapore the difficulties which impeded collections are only just beginning to be surmounted. The Chief Engineer adverts at length to certain cases in which the collection establishments in this district were charged with oppressive acts in realizing the water-rates due. The matter was brought to the personal notice of the Lieutenant-Governor when on tour, and a searching enquiry by the Collector and Superintending Engineer followed. The allegations made

were completely disproved; but in the meantime collections almost ceased, and low prices, the prevalence of malarious fever, and the time taken up in issuing leases in place of those which expired, have militated against the realization of the arrears which had accumulated. The system which was last year introduced in Shahabad, under which an experienced Deputy Collector was placed in direct charge of the collecting department, has been specially successful, having received much personal attention and supervision from the Collector of the district: the amount received during the year for water-rates was Rs. 5,30,706, against Rs. 3,09,980 in the year preceding, and for the first time since irrigation operations were commenced, there is a decrease in the balance remaining to be collected at the close of the year.

During the year under review the working expenses, direct and indirect, amounted to Rs. 11,03,834, against Rs. 10,50,728 in 1880-81. The excess is wholly in Orissa and Midnapore, there having been a decrease of Rs. 14,015 in the charges on account of the Sone canals. Heavy floods in Orissa, which necessitated special repairs to the embankments on the Byturnee river, and large expenditure on the dredging plant used on the Midnapore canal, were the chief causes of the increase. There was a decrease in the total irrigated area, and this occurred wholly in Behar. The falling-off in the area watered by the Sone canals may for the most part be ascribed to seasonable rainfall, which, to quote the report, was 6·17 inches in the kharif season, and 4·11 inches in the rubbi season, more than in the previous year. The decline in rubbi irrigation is, however, partially due to the substitution of kharif for rubbi crops wherever irrigation can be secured, and is observable, though in a less degree, in Orissa.

The navigation receipts of the year amounted to Rs. 3,42,876, and thus exhibits an excess of Rs. 63,892 over that preceding. This increase occurs chiefly in the receipts from the canals comprising the Sone project, but with the exception of the tidal canal, there has been development everywhere. The receipts from the transport service, which are included in the above figures, reached Rs. 91,606, against Rs. 67,387 in 1880-81. It is contemplated to gradually transfer this service to private enterprise, and a beginning has already been made, the Calcutta Steam Navigation Company having, from the 1st January of the current year, taken over the steamers on the Midnapore canal. The results of the year's working are the most successful yet experienced, and though up to the present time irrigation works have failed to defray the charges for interest payable to the Government of India, the returns are increasing, and warrant the expectation that eventually the Orissa and Sone canals will cease to be a burden to the province. Estimates for extending the distributary system in Orissa have been submitted to the Government of India, and as at present 106 of the 214 miles of canal in that province are absolutely without any means of distributing the water they carry over the country they are supposed to irrigate; it is hoped that sanction will not be withheld. If accorded, it may reasonably be expected that the new distributaries will be as successful as those now existing, in which case the receipts will suffice to cover the interest charges on the entire capital expended.

The Sone canals require time to develop; the largest proportion of the revenue is at present derived from the Arrah canal and its branches, and it is thought that there is no reason why irrigation should not become equally developed on the remaining branches as their advantage becomes better known.

THE FOREST ADMINISTRATION OF BRITISH BURMAH.

THE Chief Commissioner's resolution on the Forest administration of British Burmah for the year 1881-82 testifies that excellent work was done by the department during that period.

The area of reserved forest was increased by 886 square miles, making the total reserved area stand at 2,876 square miles at the end of the year, which is distributed between

the Pegu and Tennasserim circles in the proportion of 2,440 square miles to the former, and 436 square miles to the latter. With the exception of 47 square miles reserved in the Tennasserim circle, the work of reservation during the period under notice appears to have been entirely confined to the Pegu circle. The new reserves were the Mindome Yoma and the Yagthe in the Prome division, the Upper and Lower Tramayee in the Bassein division, and the Kyaukewasin and Saing in the Toungoo division. The work of reservation is said to be far advanced now, chiefly in the Pegu circle, where it is considered to be completed on the west slope of the Pegu Yoma. In both the Pegu and Tennasserim circles further tracts have been examined in view to declaring them reserved forests. The local administration considers that the reservation of forests has been most successfully carried out, and that the officers employed on forest demarcation have been very careful in ascertaining and examining the claims of those interested in the forests proposed for reservation. Every consideration appears to have been shown to the villagers whenever their removal has been rendered necessary, and they have been allowed to move at their convenience, ample compensation being also granted to them for the trouble involved in shifting their dwellings.

Of the total area of 115,982 acres under protection from fire, only 1,906 acres were burnt during the year. In 1880-81, 19,363 acres were burnt out of 96,218 acres under protection, the area actually protected being only 76,858 acres. The improvement in the year under notice is therefore very noticeable, but although the area protected is so much larger than in 1880-81, the cost of protection has only increased by Rs. 780. The average cost per acre of successful protection was one anna seven pies, against two annas two pies in the previous year. There were fifteen fires during the year; most of them are believed to have been due to accidental causes, though several are also attributed to incendiarism, some for the purpose of driving game out of the forest, and others from purely malicious and mischievous motives.

The progress made in teak planting does not appear to have been very great. The total area under teak at the close of the year was 8,000 acres, against 7,131 at the end of 1880-81, or an increase of 869 acres. The planting operations are being conducted now on the toungya system, the entire area of teak toungyas at the end of 1881-82 was 4,439 acres, costing on an average about Rs. 9-13-11 per acre. The system is said to be succeeding admirably, the greater portion of the areas on which it has been tried is now stocked well with healthy seedlings, and every advantage is being taken for promoting the system. An interesting experiment was made in the Pegu circle in the Bwet and Nyanleh reserves in toungya teak planting in areas where the bamboo has flourished. The course adopted is to burn the flowering bamboos and plant up the area so burnt over with teak seedlings transplanted from nurseries. An area of 450 acres was planted in this manner during the year, and the results have been very successful. Further operations on this system are to be tried during the current year. The results of the experimental cultivation of exotic trees at Mergui and Tharrawaddy have been on the whole successful. The plants of the *Pana*, India-rubber tree, and the *Ceara* trees are said to be growing well at Mergui, while such of the mahogany plants in Mergui and Amherst as have escaped the attacks of insects are making excellent growth. The cinchona plantation at Thandoung has not hitherto promised well, and that at Pyoonchoung has done so poorly that orders have been given to abandon further outlay on the experiment there. The local administration is desirous of obtaining the advice of an expert as to what should be done to secure greater success, and it is hoped that Dr. King will be able to visit Burmah shortly, if his services can be spared by the Bengal Government.

In the account under girdling operations, we see that 24,409 trees were girdled during the year, at a cost of Rs. 6,210. During the coming season it is believed that about 11,000 teak trees will be girdled, and it is estimated that there will then remain about 26,000 to 30,000 trees, the girdling of which will extend over two years.

The total revenue of the Department amounted to Rs. 22,31,804, as against Rs. 15,16,613 in 1880-81, or an increase of Rs. 7,15,191. The large increase has occurred in timber and other produce removed from the forests by

Government agency. The total number and quantity of logs and pieces of timber of all kinds extracted by Government agency during the past two years were:—

| | Number of logs and pieces. | Quantity, Tons. |
|----------|----------------------------|-----------------|
| 1880-81 | 35,487 | 18,910 |
| 1881-82 | 198,789 | 50,517 |
| Increase | 1,63,252 | 31,607 |

Of this timber 43,630 logs and pieces, and 29,615 tons were teak. The extraction and utilization of other timbers than teak is now being largely taken to, a course which is viewed with great satisfaction by the local administration as likely to help to expand the business. Owing to the decline in the production of cutch, there has been a large falling-off in the receipts under the head of "minor forest produce." There were only 2,611 cauldrons at work during the year, as against 7,275 cauldrons in 1880-81, and the amount realised for permits to manufacture cutch was Rs. 48,486 against Rs. 81,066 in the year preceding. The decrease we observe is attributed to the fact that the cutch supply outside reserves is nearly exhausted.

The total expenditure of the year amounted to Rs. 11,50,223 against Rs. 7,12,568 in 1880-81, the increase being principally due to the enhanced cost of extraction of timber by Government agency, owing to the larger quantity brought out of the forests.

UTILIZATION OF SEWAGE.

SO much has been said and written on this great social problem by physicians, sanitarians, political economists, and scientific agriculturists of eminence, that it is scarcely possible to meet the subject without trenching on previously published opinions. The late revelations, however, concerning the state of the Calcutta sewers by Mr. Thomas Jones, renders necessary a clearer comprehension of the laws of hygiene than can be gained by a study of the logic of disturbed municipal functionaries, who object, it appears, to learn through exact observation and examination the cause of deficiencies made palpable by their very vileness. We have already learnt enough to know what gave origin to the December stench, accounted for then by the horse-droppings and other theories, in the absence of easily accessible and since ascertained conditions. These conditions brought to light by Mr. Jones point to some defect in the construction of our sewers, or neglect on the part of those responsible for their control, and to the surmise that for some time past these sewers have, instead of contributing to our health and comfort, been converted into active generators of zymotic poisons. Sewers are considered by some to be the perfection of sanitary skill, and we are far from disputing their value, when properly worked, for we have exact statistic data to show that wherever they have been introduced and rigidly looked after epidemics have ceased. But we have seen, not in this country alone, that we cannot safely rely on having the ideas of the projectors of these works carried out; that consequently it becomes a matter of importance to seek for additional measures to meet conditions which, under similar circumstances to those locally revealed, might again occur. To secure such measures we must put aside all question of expense until such time as complete safety has been provided for, when it will be our duty to consider whether, by the utilization of the waste organic matters operated on, we can recoup either wholly or in part the money spent. In order, therefore, that our judgment may be facilitated respecting such extra measures, it becomes necessary to shortly refer to those in use in European cities. We allude of course to the various precipitation processes in operation at London, Liverpool, Leicester, Birmingham, Bradford, Coventry, Tottenham, Swindon, and other places, one or two examples of which taken from papers by David Forbes, F.R.S., and Dr. Wallace of Glasgow, will enable us to comprehend at a glance the idea governing them, as well as inform us of their cost and value. "Among the towns where precipitation is in use," says Dr. Wallace, "none is more worthy of attention than Leicester, the population of which is about 120,000, while the sewage amounts to 7,000,000 gallons per day. The quantity of lime used is 20 or 30 cwt. per

million gallons, and nothing is obtained for the sludge, which has hitherto been employed, almost exclusively, in making up land in the immediate neighbourhood of the works. The cost of working, for lime, fuel, and labour, is £2,800 per annum. The whole of the sewage requires to be pumped 26 feet. The precipitation is effected in a series of very large tanks and settling ponds, and the effluent is further purified by filtration through an osier bed three acres in extent. Coventry has been working for some years Dr. Anderson's patent in which sulphate of alumina, with enough lime to throw down the alumina, is employed. This latter process yields a sludge having three times the phosphatic value of that precipitated by lime alone. "Whatever system," continues Dr. Wallace, "of precipitation is adopted, the disposal of the sludge is one of the most important elements in the calculation of the cost." This is a question, however, which we think in a place like Calcutta will be easily met. Against the statement by Dr. Wallace concerning Leicester, that nothing is obtained for the sludge, we have a report by Dr. Augustus Voelcker, Consulting Chemist to the Royal Agricultural Society, on precipitated London sewage; it is addressed to A. P. Price, and quoted by David Forbes, F.R.S., as follows:—

"The following is the composition of the sewage deposit, which you desired me to analyse:—

| | |
|---|-------|
| 100 parts of the dry sewage deposit contain moisture, | |
| less in drying at 212°F. | 3.98 |
| * Organic matter and water of combination | 20.11 |
| † Phosphoric acid | 28.52 |
| Lime | 13.09 |
| Alumina, and oxide of iron, and a little magnesia | |
| and alkaline salts | |
| Insoluble siliceous matter | |

100.00

* Containing nitrogen 0.57, equal to ammonia 0.69.

† Equal to tribasic phosphate of lime 62.26.

The whole of the phosphoric acid, I may state, occurs in this manure in the shape of precipitated phosphates, a form I need hardly say in which the phosphates are readily available by plants. The presence of a large amount of water of combination in the deposit, that is, water which is not expelled on drying at the boiling point of water, shows that the phosphates with which the water enters into chemical combination, and which does not escape at 212° F., are not likely to return readily into the ordinary and, comparatively speaking, ineffective condition in which they exist in phosphatic minerals. Being obtained by precipitation from their solution, the phosphates are present in the deposit in a very efficacious form. * * *

It possesses valuable fertilizing properties, and in my opinion a sewage manure, equal to the sample analysed by me, will command a ready sale at £7.7 per ton. Believe me, yours faithfully,

(Sd.) AUGUSTUS VOELCKER.

According to Forbes, the estimate of value here given is due in a great measure to added phosphates, crude phosphate of alumina being used as the precipitant; about £2-10, however, per ton, would be the value of the material recovered. It is, therefore, reasonable to suppose that a manure representing even one-fourth the percentage of phosphates noted, would command a ready sale at Calcutta. The purifying action of these precipitants is due, says Forbes, and as we ourselves well know, to the chemical reaction between the alumina salts, and the organic matter in the sewage, by which compounds are formed, especially with the nitrogenous or albuminoid constituents, more or less insoluble in water. Putrefaction is thus checked, and the evolution of foul gases carrying into the atmosphere we breathe the germs of cholera, typhoid, and small-pox rendered impossible. We cannot pursue our reflections on this subject without a whole train of thoughts occurring to us, and the germ theory of disease—no longer a theory in our opinion—is that which forces itself upon us at every turn. As it appears that certain municipal functionaries are inclined to disregard the opinion of authorities on this point, it may be well to quote Tyndal at this place. "Let me state," says that philosopher, "in two sentences the grounds on which the supporters of the germ theory rely. From their respective viruses you may plant typhoid fever, scarlatina, or

small-pox. What is the crop that will arise from this husbandry? As surely as a thistle rises from a thistle seed, as surely as a fig comes from the fig, the grape from the grape, and the thorn from the thorn, so surely does the typhoid virus increase and multiply into typhoid fever, the scarlatina virus into scarlatina, and the small-pox virus into small-pox." Putrescent sewage matter is the soil in which zymic infusoria abound. Since then there is every reason to believe that these fermentative organisms can transform themselves under peculiar conditions into different ferments, which, fructifying in this soil, yield germs endowed with distinct poisonous properties, the idea of destroying the chance of their evolution in the first stage, becomes of vast importance. Water, according to David Forbes, Dr. Wallace and others, has *per se* no purifying action whatever; it merely acts as a diluent, and serves to carry out the first principle of sewage engineering, *viz.*, the rapid disposal of fecal matter, into the nearest tidal river or to some centre where sewage irrigation is practised. Here another thought of importance occurs. Some sanitarian has said that by the former means of disposal, we pollute our streams to such an extent that they can no longer furnish water fit for either man or beast to drink, or fishes to live in. Happily in Calcutta our great arterial drain, the Hooghly, offshoot of the holy Ganges, is not utilized for this purpose. It appears, however, no less certain, in the absence of special protective measures, that wherever the city sewage is conveyed, its properties and effects are not altered. Discharged as it is into the salt lakes, some miles beyond the city, and thence as supposed into the Byddadruee, a tidal stream, we conclude that the effects and influences of saline matter, the atmosphere, tide and current, must render it innocuous. Are we, however, satisfied that this is the case? We must admit of course that the matter is rendered, so far as we in Calcutta are concerned, inoffensive, but we may have wafted back to us, when south-easterly winds prevail, disease germs of varied potency, which indeed, the characteristic unhealthiness of the intervening suburbs points to. The closer, in fact, we examine the question, it will appear that we cannot purchase safety at a cheaper rate than the people of Coventry and Leicester. We have seen that the defecated sewage of these towns is rich in all the elements essential to plant growth; that it is further of a compact nature, and may be used for raising the land. Why, then, in the case of Calcutta, where a natural impulse urges us to save it for agriculture on the one hand, and for our better protection from the action of tidal waves on the other, should we not venture upon this second, and evidently conclusive, step in sanitation? We know that every grain of wheat, every grain of rice, and other seeds, every chest of tea and indigo, every bale of cinchona and numerous other products which leave the country contribute year by year to the exhaustion of the soil. This is an oft-told tale, but it cannot be too often conveyed to the native mind, and to the minds of European settlers who have large interests at stake. This sewage precipitate is the manure *par excellence* for indigo, by reason of the large amount of ammoniacal matter it contains, and for wheat and tea, by reason of its richness in phosphates. The demand for such substances, however, must be created. The obvious duty, therefore, of the Calcutta municipality, if they think fit to adopt any of these additional methods for the prevention of the putrefaction of waste organic matter, is to do so, at first, without hope of profit. That such measures are necessary there can be no question, especially since the president of the Calcutta Council maintains that undulatory strata of almost concrete sewage, varying from six to eighteen inches, does not retard the flow of matter, and the desired accelerative action of the tide. Putting aside altogether this argument, which we might make much of, and bearing in mind simply that this concrete matter—itsself putrescible—forms a series of cesspools wherein recent fecal matter becomes deposited, ferments and fills the drain with deadly gases of greater tension than the superincumbent atmosphere, we must instinctively admit, not alone from their very palpableness, that such vapours find their way by perhaps a thousand different outlets, into the atmosphere, and that if we do not die, it is because fate keeps us without the zones within which zymotic germs find egress. It does not fall within our province

to point out which method of sewage irrigation or precipitation would be most applicable to Calcutta, but we venture to suggest a means of its profitable disposal when so treated, and we do so, bearing in mind the wish of the present Government to raise the native to a better estimation of himself; and in doing this we need but refer to Akbar's instructions to his collectors of revenues with regard to agriculture, which were as follows:— "The collector must consider himself the immediate friend of the husbandman, be diligent in business, and a strict observer of the truth, being the representative of the chief magistrate. He must transact his business in a place to which everyone may find easy access, without requiring any go-between His conduct must be such as to give no cause for complaint. He must assist the needy husbandman with loans of money, and receive payment at distant and convenient periods. When any village is cultivated to the highest degree of perfection, by the skilful management of the head thereof, there shall be bestowed upon him half a biswah out of every biggah of land, or some other reward proportionate to his merit. Let him learn the character of every husbandman, and be the immediate protector of that class of subjects. Let him promote the cultivation of such articles as will produce general benefit and utility, with a view to which he may allow some remission from the general rate of collection. In every instance he must endeavour to act to the satisfaction of the husbandman." This quotation, we think, renders our plan at once obvious. Let the Government purchase the Municipal produce, insist on its use, and recoup themselves at distant and convenient periods by imposing a slight tax on the calculated increase of produce, keeping in mind, however, at the same time, the principles laid down by Akbar. They will thus in a simple way conduce in a great degree to the spread of agricultural knowledge, and prevent the inhabitants of large towns being overtaxed to insure life, when, as it is, they are heavily burdened. They will contribute to a reduction in the price of food-stuffs, by promoting their increase, and so, to contentment. Above all, they will contribute to their own safety—for zymotic germs are no respecters of persons.

EDITORIAL NOTES.

FROM the report of the experimental farm at Bhadgaon for the half-year ending December last, we observe that the area cultivated with cotton was 210 acres, or an excess of 58 acres over the area of the preceding year. Notwithstanding the excessive rainfall of the season which injured some of the crops, the out-turn is good on the whole, the average yield of clean cotton being estimated at 200 lbs. per acre. In regard to the prospects of cotton in the district, Mr. Stormont, the superintendent of the farm, thinks that the produce will be equal to that of the year preceding in quantity, and considerably superior in quality, owing to the almost entire absence of the Waradi or Deahi variety, which is now scarcely cultivated anywhere in the district. From the results of his experiments with a new cotton, which was believed to be a hybrid, though subsequently it was proved that the plant was no hybrid at all, Mr. Stormont concludes that a crop or plant of any kind may be readily and largely developed and modified by cultivation. The plant in question was sown under varied conditions, in rich garden ground, on medium land, and in a poor cotton field; and with the results that, under the first, it maintained its peculiar character, the second was irregular and below average, while the third failed entirely.

The area under *bajri* and *jowari* was 106 acres: the abundant rainfall of the season was highly beneficial to both crops, and the yield would doubtless have been large, were it not for the damage done by locusts, by whose ravages half the entire crop was destroyed. The cultivation of wheat was also, we see, more extensively carried out during the period under report, and the crop promised to turn out well. Consignments of the farm wheat have, we observe, been sent to British Burmah and Mysore for cultivation. In Burmah, it is said that it is intended to

attempt its cultivation in lands which are rendered unfit for paddy cultivation; owing to their being inundated during the rains. The cultivation of the early amber-cane has also been attended with success, the *jagres* and *treacle* manufactured from it is said to be of superior quality, and the latter is to be utilized for making candy sugar, for which purpose it is believed to be suitable.

We see that the exhibition of farm bulls at the recent agricultural show at Ahmednugger has resulted in a demand for superior animals in that district, and some animals are now being sold at prices ranging from Rs. 100 to Rs. 125 each. A two-score flock of Dumba sheep was also added to the live-stock of the farm during the half-year, but from the experience already derived in the breeding operations carried on, on the farm, the superintendent does not think that animals of pure blood will take to the climate. The cross between the country ewe and Dumba ram has, however, it is said a good constitution, and retains to a large extent the fineness of wool of the pure Dumba.

We observe it mentioned that the employment of saw-gins for cotton-cleaning has, through the experiments shown on the farm of their effectiveness for this purpose, found much favor amongst private firms and companies.

In one district of India alone, half the cattle, or 250,000 head, died from starvation in 1877. Disasters of this sort have resulted from an increase of the population, which advances further and further into the jungle, bringing into cultivation cultivable waste land, which formerly served the purpose of village grazing grounds. Precisely the same encroachments occur in Europe from the same cause—that of increasing numbers. But owing to the greater constancy of the weather in temperate climates, the effects there are not serious. In such places, compensation for the lost grazing ground is found in the increase of cultivated fodder crops, upon which reliance can be placed from year to year. But in India, things are different. In unirrigated tracts—that is, over a very large part of the country—if droughts occur, and we know that they do so periodically, the fodder crops wither and die, and the cattle, having no longer any jungle to which to turn, perish miserably. The Government of India is therefore setting itself to work to remedy this state of things, by protecting and enclosing forest grazing lands. This will serve a double purpose. The long-rooted grasses deriving a supply of moisture from below, and the shallow grasses protected by shade above, will then furnish food for cattle, while the bushes and smaller trees will reproduce themselves by seeding, and provide fuel. Something has already been done in this way in Ajmere; and the results, after five years only, are said to be most encouraging, the appearance of the hills and countryside being quite altered. Averse as the villagers must be at the outset to a proceeding which encloses even a portion of their grazing lands for a time, they come to see the advantages of it when drought is upon them, and will, no doubt, before many years have passed, be allies, instead of opponents, of a measure designed solely for their benefit.

In Ajmere, side by side lie protected fodder reserves and unprotected jungle, and the difference is most striking, though the enclosures have existed so short a time. "The first are covered with an almost impenetrable thicket, chiefly composed of shoots edible by cattle. The second are practically devoid of all vegetation, and appear to be mere heaps of rock and stone."

ONE of the changes resulting from the reconstruction of the Madras Agricultural Department is the retirement from the service of Mr. K. Schiffmayer, Assistant Superintendent of Government Farms. Mr. Schiffmayer is a graduate of two German Agricultural Colleges, and a pupil of the late Baron Liebig, whose lectures he attended when a student of the Royal Polytechnic, and of the University of Munich. Mr. Schiffmayer came out to India in 1873. He was especially engaged with the view of being employed in connection with district farms, the establishment of which was then under consideration. District farms having never been opened, the services of Mr. Schiffmayer were utilized on the Saidapet Farm and the Agricultural College of that

place. When engaged in the chemical laboratory, he was seriously injured by an explosion of chemicals, which led eventually to his retirement. Mr. Schiffmayer possesses a farm near Bangalore, and intends, after having recruited his health, to use the same as an experimental and acclimatisation station.

A SUPPLY of 62lb of Carob seed was received from the Director of the Department of Agriculture and Commerce, North-Western Provinces and Oudh, in the month of August, and was sent to the Divisional Commissioners and Conservators of Forests in the Bombay Presidency for distribution among the District Collectors and Forest Officers for cultivation in localities where it was likely to succeed. Reports regarding the result of the experiments were called for, and have been received by the Bombay Government; and the following is the general results of experiments:—

The Acting Conservator of Forests in Sind reports that the Carob seed sent to him was distributed amongst the District Forest Officers; that experiments made with it in the Sukkur circle in Rahnja nursery have failed; that another trial was also made in the Sonda nursery in the Jerruck circle, where, on 31st July 1881, about 11 tolas of the seed were sown broadcast; and again, on the 5th October, 14 tolas more were similarly sown; that of the July sowing only 9 seeds germinated, but the August lot produced a considerable number of plants, of which 68 have survived; and that the 9 July seedlings have reached heights of 33, 33, 22, 20, 16, 14, 11½, 9, and 8½ inches, and the August plants vary from 1 to 14 inches, but the greater number stand from 5 to 8 inches. The Conservator states that all the plants were protected by mats from the frost during the cold season, and adds that, when once these plants have established themselves in the soil and have sent their roots deep enough to reach the lowest level to which the moisture sinks when the floods subside, they should be able to exist without artificial irrigation or protection; and that at present they are too small, and he thinks it would be premature to express an opinion as to their flourishing in Sind or not.

The Superintendent of the Economic Garden at Hyderabad reports that two-thirds of the Carob seeds received by him was sown in pots on the 28th October 1881. The seed came up well, but a great number of the young seedlings were lost on account of his having (for want of small pots) to transplant them at once from the seed pots into nursery lines. Only 45 plants remain alive; they are quite healthy, but the largest plant is only about 7½ inches high. The remainder of the seed was sown on the 7th July 1882, and is beginning to show signs of germinating. Mr. Strachan states that he has tried this plant twice since the garden was shifted from Salaru to near Hyderabad, and five or six different times at Salaru both in seed-beds and in pots, and has found the latter plan most successful, and adds that, so far as the suitability of Carob to the soil and climate of Hyderabad is concerned, it will grow, but the slowness of its growth will prevent its being of much use except as an ornamental shrub in gardens, and the cost of rearing a plantation of Carob in Sind would be very great.

In submitting Mr. Strachan's report, the Commissioner in Sind observes that the results of the experiments tried at different times with Carob seed in Sind seem clearly to show it is not likely to grow well in that province, or be successful as a tree for purposes of trade.

The experiment has proved somewhat successful in "Rutnagiri and Kanara. It has been a complete failure in Kaladgi, and the report for Belgaum is also discouraging. It will probably succeed fairly in the moist climate of the Ghaut and Konkan Districts, Rutnagiri, and Kanara."

The Conservator of Forests, Northern Division, submits reports from the District Forest Officers of North Thana, South Thana, Khandesh, Nasik, Ahmednugger, Poona, Satara, Sholapore, Surat, and Panch Mahals, from which it appears that the experiments made by these officers in the cultivation of the seed generally failed except at Satara, where almost all the seed sown in pots germinated, the young plants being now healthy and about nine inches to one foot high, and at Sholapore where the seed sown resulted in 25 healthy seedlings, which are now one inch high.

The Conservator of Forests, Southern Division, reports that the experiments made in his division have proved utter failures everywhere except in Belgaum, where better results were obtained, and where there are 318 seedlings now remaining of an average height of four inches, but what effect the late heavy rains have had on them remains to be seen.

THE report from the Manager of the India-Rubber Works Company, Silvertown, Essex, upon samples of rubber obtained from trees of *Hevea brasiliensis* and *Castilloa elastica*, growing in the experimental garden at Heveratgoda in October 1882, and sent by the director, Ceylon Botanic Garden, to Kew for transmission to Messrs. Silver and Company, is a very satisfactory one.

As far as quality is concerned, the *Castilloa* produced in Ceylon by the three species of South American rubber-trees introduced by the Indian Government in 1876-77, is in all respects fully equal to that collected from the wild trees in their native districts.

Hevea Rubber.—As far as chemical examination goes, this rubber differs in no respect from the better description of Para bottle rubber, except perhaps in having a little more water imprisoned in it than is usual with well-seasoned Para. The method of preparation, as each layer in Para bottle rubber is partially dried when held over the fire as practised in Para, may explain this. A portion of this rubber well washed and dried gave a loss of 16·7 per cent. The amount of ash obtained on incinerating a portion of the unwashed sample is 0·7 per cent, which is about one-half that from the Brazilian product. There is a great similarity in the composition of the ash of the *Hevea* and the Para bottle rubber. The ash from the washed and dried *Hevea* is 0·6 per cent. This sample is almost entirely free from extraneous matter. On digestion in alcohol it yields only a slight coloration. Like Para rubber, its fresh-cut surfaces show a slight acid re-action, easily removed by washing. The washed product is free from taste and smell, and turns a dark colour on drying similar to ordinary Para rubber. As far as can be determined on so small a sample, there is reason to believe that as regards strength and elasticity, it would be fully equally to good Para India-rubber.

When mixed with the suitable proportion of sulphur and vulcanized, it possesses great strength and elasticity.

Castilloa Rubber.—On washing and drying a portion of this sample the loss is 12·3 per cent, so it is necessary to use warm water in washing this rubber; it becomes, on drying, much darker and shorter than para rubber. It has a bitter taste, which is not removed on washing. The unwashed sample yields 1·9 per cent ash; the washed sample gives 1·2 per cent. The shortness of this rubber would restrict its use to some slight extent where tensile strength or tenacity is required. When mixed with the usual proportion of sulphur and heated, it vulcanizes well, but imperfectly, and is devoid of strength, characteristic of the better kinds of rubber. Nicaragua rubber is not at present met with in this country to any great extent, but there is no doubt that the purity and general qualities of this sample would gain for it a favourable reception, even if our supplies from present sources were more adequate to our demands. The chemical analysis of the ash of the *Castilloa* shows that there is no very marked difference in the mineral constituents of the juices of the *Hevea* and *Castilloa* under the present system of cultivation.

At a meeting of the German wood-pulp manufacturers a communication was read from Mr. Keller, describing how he first discovered wood-grinding for pulp. His first idea of taking wood as a substitute for rags was conceived by reading of the wasp's nest. Experiments with sawdust were, however, fruitless, and a remembrance from early days brought him to try wet grinding, using a common grinding stone for the purpose. He then obtained wood-pulp, and straining through a cloth, pressing between a book, and drying, the first sheet of wood paper was made within four hours. He finally built a small grinding apparatus, taking his wife alone into his confidence. He made several attempts to obtain a partner, but in vain. In 1845 he received a patent from the Saxon Government, and shortly afterwards was successful in leading

a paper mill near Marienberg, but the owner became bankrupt, and although Keller afterwards bought the property, he was unable to carry his ideas into execution owing to straitened circumstances. Shortly afterwards, Voelter heard of his invention, and after some interviews became possessor of it for the sum of 700 thalers and a participation in profits. The year 1848-49 brought the Revolution, and 1850 a flood which completely stopped Keller's mill. In these circumstances he applied to the Saxon Government and received an advance of 2,000 thalers. An artificial "leech" of India rubber was one of the novelties invented by Keller in those hard times, but this was sold to an American for seventy-five dollars. Voelter, in the meantime, had not succeeded in deriving any profit or success, and finally the compact was dissolved, Keller being obliged later to give up his mill to the creditors. Voelter's further success is well known.

AN American contemporary says: Sorghum-sugar enthusiasts are properly alarmed at the perfection glucose has attained in the hands of skilful chemists, who have succeeded in getting 24 pounds of pure, dry, white, absolutely crystallized glucose, closely resembling loaf sugar, from each bushel of corn of 56 pounds, at a cost so low that by-products pay all the expenses of the manufacture, enabling the company to sell it for from 2 to 2½¢ a pound in large quantities, and half-a-cent more for small. It looks much as if the sorghum men must make a fight to have this glucose sold under its own name, and not as cane sugar, which it is now used to adulterate and cheapen.

THE *Mexican Financier* has recently called attention to the value of the well-known American agave, a species of the aloe plant, found everywhere in Mexico, and numbering not less than thirty varieties. The fertile plains called "Los Llanos de Apam" have long been noted for the special excellence of the pulque, to whose production the plant is most exclusively devoted. Situated between Puebla and the city of Mexico, these plains are covered, as far as the eye can reach, with these flourishing plants, each of which produces pulque, the natural exudation of the plant, to the value of about six dollars, and then is supposed to have lost all its utility. In the district of Tequila no pulque is drawn from the plant, because its special virtues enable it to produce the brandy named after the district, and widely used throughout the country. This Tequila brandy is made by an old system dating back to the days of the Aztecs, and which consists of roasting the bulbs in a furnace dug in the ground. This gives a sweetish liquor, which, when cleared and subjected to the further processes of fermentation and distilling, yields the favorite brandy. But beyond this, no use is made of the plant. The same is the case in every district of the country where pulque and tequila are produced, and so notorious is the general ignorance or indifference to any further use of the plant, that its destruction is general when it has once passed its period for yielding either of these products. And yet there is very facility for utilizing the plant in at least four distinct industrial products, each of them very important and promising large returns. Next to pulque and tequila, the plant can be made to yield an excellent quality of molasses, by clarifying the sweet decoction of the bulb. Distilled, this becomes brandy; undistilled, it yields molasses equal, if not superior, to any pressed from sugarcane. The peninsula of Yucatan has grown famous for its production of henequen or jute. The leaves of the maguay plant everywhere in Mexico, when pressed, yield a fibre in all respects equal to the best Yucatan jute. Various experiments, though on a small scale, prove this. Ropes are in use in a thousand districts of the interior, made from these leaves, and of unequalled strength and excellence. The peculiarities of soil and climate are of some importance in considering the uses of this fibre for cordage, but even where it is found somewhat inferior in this respect, which is rarely the case, the pressed leaves yield a pulp absolutely unequalled for making paper. The paper mills of Belem have repeatedly produced an excellent quality of paper made from this pulp, and it has not made its way into commerce, only because no one has as yet taken hold of this virgin industry, and produced the pulp in marketable quantities.

THE *Live Stock Journal* says: It is important in all branches of industry to consider the sources of income, and their availability at short periods. Sheep afford a *double income* annually,—lamb and wool,—and they are usually about equal in value. The power of assimilating food is one of the most important of animal functions. Sir J. B. Lawes, in his experiments to determine the percentage of food utilized, or stored up, by different animals, found that sheep stored up, in increased weight, 12 per cent of dry food consumed, whilst cattle only laid up in increased weight of 8 per cent.—that is, 8½ pounds of dry food increased the weight of sheep as much as 12½ pounds did the weight of cattle. So that, if these experiments are to be trusted, sheep must be considered as excellent utilizers of food—as producing, at least, as many pounds of mutton, besides the wool, from a given quantity of food as can be produced of beef; and, as the best mutton brings as high a price as the best beef, it would appear, on this basis, that sheep would give the fleece an extra profit over cattle. On this view sheep, on suitable lands, must be considered among the most profitable of farm stock. It is true the dairy cow brings her profitable flow of milk to offset the fleece of the sheep; but the good dairy cow does not lay on flesh while in milk, as does the sheep while growing the fleece.

THE value of the eggs annually consumed in the United States is stated to be \$75,000,000. There are many ways of preserving them, when plenty and cheap, for the time of scarcity, but very few have proved to be entirely successful. A correspondent of the *American Dairymen* says that after trying several methods, he has found that eggs covered with melted paraffine kept the best of all, and those of them that were put down in weak brine, in which they sank to the bottom, kept better than others packed in dry salt or in plaster. He mentions also a German preparation of salt, saltpetre, and borax, which however is patented in America. He had some eggs put down in this for five months, and they were equal to fresh eggs, even when boiled for eating, a very delicate test, as eggs very soon exhibit any staleness when so cooked. An omelette made of eggs put down in this solution was very good, and so was one made of eggs a year old kept in paraffine, as was also a sponge-cake made of beaten eggs.

THE life of telegraph poles is estimated as follows: Cedar, 16 years; chestnut, 13; juniper, 13; spruce, 7 years. Cedar, chestnut, and spruce are used in the Northern States, juniper and cypress in the Southern States, and red-wood in California. Poles cut in the summer will not last as long as those cut in the winter by five years. Soil and climate, of course, make a difference with the life of poles.

MR. C. BENSON, Assistant Superintendent of Government Farms in the Madras Presidency, having obtained permission to visit the works of some of the leading Agricultural Implement Makers, and the Experimental Farm at Rothamstead, has submitted the results of his investigations, in the course of which he makes the following suggestions:—"I would venture to point out the extreme desirability of doing everything within the power of Government, to introduce into India an improved plough suited to the conditions of the Indian cultivator, as regards his poverty and the strength of his cattle. As far as my experience goes, no thoroughly satisfactory plough has yet been made, and it is probable that in various parts of India, slight modifications may be required to meet the ideas of the ryot, but for the greater part, as now, one general form of plough would meet the demand. Again, that it is desirable to strain every nerve to create a demand for improved ploughs, no one who has studied Indian agriculture, and the effect which the improvement of it would have as a means of preventing famines, can doubt. The Indian farmers also cannot draw on the world for supplies of manure to replace withdrawals made by the crops raised as the English farmer does, but must rely on indigenous resources. The greatest store of these lies below the surface stratum of soil at present tilled, and to reach this, the ryot requires a better tillage implement than he now pos-

asses. I, therefore, venture to urge that samples of the light ploughs made by the chief makers should be obtained and sent out to the different provinces of India for a thorough trial, so that, when the results were reported, with suggestions for the modification, if necessary, of any of the ploughs which appear suitable, or with samples of what is required, together with information for the use of the manufacturer of the price at which similar ploughs can be made up in India, the question can be solved, whether a cheaper article (in every sense) can be obtained for the ryot in England or from native makers. It would also hereafter not be out of place, nor bad economy, for Government to dispose of a considerable number of ploughs of the pattern selected to the ryots in different parts of the country at reduced prices, themselves bearing the actual cost.

"A trial, such as I have ventured to suggest, would be of the greatest value, both for solving the question referred to above, as well as for putting within the reach of the ryots a suitable and tolerably efficient plough. The cost would not be great, but the trials would have to be conducted most carefully and under as varied conditions as possible, and would require the assistance of an engineer and an agricultural expert in either case.

"Besides the urgent want of a good plough for general purposes, there is little scope for agricultural machinery in India, the native implements being either sufficient or capable of easy improvement. Exceptions may be mentioned in a low priced simple winnower, a seed drill with the power of controlling the seed supply and depth of sowing, not now possessed by the native drill, and an implement suited to the operation of breaking up black cotton soils to a great depth in order to eradicate the strong deep-rooted grasses with which they become overgrown."

In North India, the Government of the North-Western Provinces are carrying out the latter operation with a set of Fowler's double engine steam ploughing tackle.

In the Bellary district, a large demand sprang up last year for strong heavy ploughs for this purpose, and a native merchant ordered out over 300 of different patterns from Sweden to meet it. The ploughs obtained, although they can do the work desired, are not the form of implement best suited to the object in view, and, acting on information I gave them, Messrs. Ransomes have put in hand a special implement, or rather a form of plough, for the purpose, which will weigh about 150 lb., have two long handles, one wheel, all parts wrought iron, steel digging breast, and share, trussed beam, and made to work about 12 inches deep, and to cost about £4. This they also intend to send out to Madras, with a request that it may be tried later on in the year. It is very desirable that this should be encouraged, as such an implement would be very valuable in the large tracts of country where the black cotton soil prevails, and the operation is necessary, for with the rough native implement now used, it is extremely costly and tedious.

It was purely accidental that the order went last year to Sweden, and if the English agricultural implement makers were kept fully informed of what was passing in the agricultural world in India, they would in all probability be able to compete with the Swedish manufacturers, where prices are generally more favorable. For this purpose, I would urge that all the leading firms should be regularly supplied with all reports, &c., on the agricultural operations conducted by Government in India, and especially with reports on the agricultural systems of different localities, such as that of Mr. Robertson's on Coimbatore (1876), and mine on Trichinopoly (1878-79), Cuddapah and North Arcot (1879), and Bellary (1880).

Besides a heavy plough for the use of the ryots themselves in the operations referred to above, a large steam implement for reclaiming large areas for use by Government, or large landholders, as has been done by the North-Western Provinces Government, would be most useful, and, after seeing "Darby's Steam Digger" at the Reading show, I went down to the neighborhood of Obelmsford and saw one of them at work. This implement seems well suited to the work, but it travels over the ground it cultivates, a principle which has never hitherto succeeded, and is still undergoing improvement as a new machine. From the report of a public trial, it appears more

economical than a steam ploughing tackle, whilst it is less cumbersome and less costly, although still the price (£1,000) charged for it is heavy for the machine as it stands. If, however, any Government in India is desirous of following the lead of that of the North-Western Provinces, I would suggest that the value and suitability of this machine should be considered before obtaining a set of steam plough tackle.

Messrs. Hornsby have been making a reaping machine for cutting indigo. It is a back delivery machine, cut 3' 3" wide, weighs 4½ cwt., and the price, packed and delivered in London, is £19. It is geared for use with bullocks and made extra strong for cutting indigo. This machine appears to have met with considerable success in the Bengal indigo districts, and its introduction at Madras might also be useful in some of the indigo districts, and would certainly be so at Saidapet for educational purposes. The same firm have been making also an automatic delivery reaper in the same style; its price is £34, unpacked.

No one who has visited Rothamstead, and seen and heard of the results of continuous corn-cropping there, can any longer be in doubt that our Indian soils have been greatly exhausted, or rather reduced in productiveness to a very low ebb; in fact, reduced to very much the same point as, if not lower than, that of the plots which have now for 30 or 40 years been growing wheat and barley at Rothamstead continuously without manure. On these plots, it is found that the average production for many years was reduced at an average rate of about one-fourth bushel per annum; but that, after the outturn had got down to about 12—13 bushels of wheat or rather more barley per acre per annum, further reduction does not go on nearly so fast. This fact explains why it is that Indian soils, with their very small produce, have not shown generally within recent years those signs of further exhaustion which have been expected by some.

The following figures show the results obtained from plots continuously unmanured:—

| | | | | AVERAGE ANNUAL OUTTURN OF DRESSED CORN. | | | |
|----------|-----|-----|-----|---|---------|-------------------------|---------|
| | | | | Fifteen Years, 1832—66. | | Fifteen Years, 1867—81. | |
| | | | | Bushels. | Weight. | Bushels. | Weight. |
| Wheat— | | | | | lb. | | lb. |
| Plot 3 | ... | ... | ... | 15½ | 877 | 11½ | 644 |
| " 20 | ... | ... | ... | 15½ | 881 | 11½ | 644 |
| Barley— | | | | | | | |
| Plot 0-I | ... | ... | ... | 21½ | 1,111.5 | 14½ | 749 |
| " 6-I | ... | ... | ... | 24 | 1,251 | 14½ | 772 |

These figures show that the average production of wheat in the second period was 27 per cent lower and of barley 36 per cent lower than in the first, taking the weights per acre.

The effect of season on such small crops as are now obtained, which it should be remembered are very like average Indian crops, is most marked. The figures for the last two years are shown below:—

may never become demonstrated to our actual physical senses. And the beautiful law known as the "conservation of energy," and of which Dr. Faraday said "it is the highest law of physical science which our faculties permit us to perceive," is another of these discoveries which explain and remove many difficulties from the path of the student. And in agricultural science, although even these laws of physics have aided greatly to make investigations more certain and more effective, yet we have not one broad and distinct law yet laid down as a basis upon which any satisfactory practice can be built up, or one which is not full of doubts and difficulties, or which is not at once fiercely combated by other investigators.

We had the mineral theory of Liebig which was popular 30 or 40 years ago; then came the nitrogen theory of Boussingault, Lawes, and others and the totally different one of Ville and some others, one displacing the other, but yet retaining some disciples and believers, who to-day are discussing and debating, and each to his own satisfaction proving the truth of his own theory. And the result is that the practical farmer is entirely without help, and is confused and misled by the multitude of opinions all differing from each other, and the uselessness of any one of them to afford him any aid in his labours in the field. In fact, it is questionable if there is one useful result that has been of any benefit to the farmer of all the investigations which have been made in the science of agriculture. The only approach to any useful service has been the valuable practical information furnished by experiments in the field conducted upon scientifically accurate principles, and by the methods of the farm rather than those of the laboratory.

The fact is, that however desirable and interesting they may be to the intelligent farmer, the results of scientific investigations are nothing more than pleasant readings and subjects for thought and mental culture, just as any other scientific matter might be; and the farmer is apt to regard them wholly in this light and therefore value them rather lightly. And it may be that this is the reason for the failure of the scientific schools of agriculture that have been instituted for the education of young farmers, as well as for the general want of respect for agricultural science among practical farmers as well as for the barrenness of results from the agricultural colleges and the experimental farms in and upon which there has been too much dependence upon strictly scientific methods of teaching and work. "A little knowledge is a dangerous thing." This is true, but not directly or positively because the knowledge itself tends that way. On the contrary, a little knowledge is good and useful and beneficial so far as it goes, if the possession of that little has not debased the mind and led it astray and unbalanced it. But this is too often the case when one has become possessed of a smattering of scientific knowledge, and that only partly learned, and has learned to believe that the little he knows enables him to deal justly with matters of which as yet he knows nothing. It is just as when the miner begins to work a vein of ore. He penetrates so far, and so far he knows. But if he is a green hand he is too apt to believe that all the ground he has blocked out, and all that between and beyond his narrow drifts and level, is rich ore like that he has been working through, and he figures up accordingly and believes he is possessed of a vast store of wealth. He therefore builds great and costly mills and spends all he has earned in machines to work up the ore which he believes is "in sight," as he may say, and within his reach. And when this is done the first stroke of his pick or the first blast shows him the barren rock where he expected rich ore, and the man's hopes and expectations are blighted and he is ruined. But the experienced miner escapes all this. The little knowledge he gains in the exploring of his mine is not dangerous to him, for he counts upon nothing further or beyond what he can take out, and actually gains, and he expends nothing from no settled belief upon any premises beyond those which he knows to be actually existing, and so escapes injury and loss. It is precisely so with the student of agricultural science. If he is not practical as well as scientific, and tests his science by actual practice as he goes along, he will very surely find himself all wrong, and will be but a blind leader of the blind.

A young man cannot learn to be a farmer at a scientific school any more than he can learn to be a blacksmith at a university. He may perhaps—and not then unless he is shrewd, level-headed, and cautious—prepare himself well to become a farmer by practical work afterwards, and acquire the ability to work more effectively because of superior mental discipline and general intelligence; but the time spent at an agricultural college or scientific agricultural school is too short for this, and the student departs from the institution with no desire to put his acquirements into practice in the field or the dairy; but unfortunately thinks he is better qualified to become a teacher himself, and so seeks a vacant chair and a professorship at some other school or college, or attempts to instruct farmers through some agricultural journal. And then it is discovered how dangerous a thing a little knowledge is.

Agriculture is eminently practical, and it can only be taught practically, or scientifically along with practice. An agricultural school or college without the best practical instruction or demonstration is as useless as a medical school without the operating room, a school of nurses without a hospital, or a school of chemistry without the laboratory. And the scientific instruction of the agricultural school should be illustrative of the practical work, and used for the purpose of explaining this. There are many farmers who desire to give their sons a good practical education as farmers, dairymen, or stockmen. But these young men are sent to farms, and not to schools, for this course of training. This is to be regretted, because the practice, the handiwork only is learned. It would be better if these young men could study at a well-appointed and a well-conducted scientific and practical school, managed on the same system as the schools of mechanics and technology are, and one where their education could be completed as far as it is carried. But, as yet, there are no such schools, although attempts have been

made to found them; and no teachers who can take the plough and turn a model furrow as an illustration of the principles upon which ploughs are made and land is ploughed, as well as teach their pupils the mechanical part of the art. These, however, are what are required.—*New York Times*.

THE DEVELOPMENT OF THE MINERAL RESOURCES OF INDIA.

AN interesting series of four lectures has just been delivered to large audiences at the Sassoon Mechanics' Institute, on the development of the mineral resources of India, by Mr. Alfred N. Pearson. The lecturer is an Associate of the Royal School of Mines, was lately resident engineer to one of the Gold Mining Companies in the Wynaad, and is at present acting Meteorological Reporter for Western India. The following is an outline of the four lectures:—

The lecturer said that at a period when one of the most gigantic mining experiments ever tried seemed to promise nothing but gigantic failure, and at a time when it was the policy of the Supreme Government to foster industrial effort, and to force the growth of manufactures, it seemed very opportune to take a look round and see what could be learnt about the mineral resources of India. There could be no doubt that, had intending investors in the Indian gold fields paid more attention to the known facts concerning the mineral wealth of the country, there would have been less rashness displayed in the adventure. And whilst it might be assumed that in the steps recently proposed for the supply of country-produced iron to State Railways, the Government of India was acting under competent advice; still it would be interesting in the light of that arrangement to notice how important in the preparation of metals were those minute practical details which were the result of long experience only. There was a general turning of attention towards the potential wealth of India, and an evident willingness to see what could be done towards its development.

The lecturer then alluded to the custom in former years of representing India by the figure of a pagoda tree, under which one could recline and pick up wealth with no greater labour than that of gently shaking the golden fruit from the richly-laden branches. Now-a-days, some people thought that either the figure had been misleading, or the tree had ceased to be so fruitful, for the pagodas no longer dropped off with a gentle shaking, and even when one stood to and shook vigorously, they generally fell but in scanty numbers. However this might be, there was no doubt that the figure grew up out of a solid ground of fact; and, indeed, it was well known that the correctness of India's traditional character was confirmed by historical evidence. The lecturer then pointed out how Sanskrit, Hebrew, and Greek writings, as also more recent ones, such as those of Marco Polo, bore witness to India's ancient mineral wealth. It was needless to remark, however, that wealth was a comparative thing. A man enjoying an income of a thousand a year, and living in a community of men who none of them earned more than two hundred, would be regarded by his fellows as a rich man; but if some of those recipients of two hundred a year were enabled by some stroke of fortune to raise their incomes to £10,000, they would begin to regard the man with his thousand as comparatively poor. India in early times occupied the position of the men with a thousand a year, while the rest of the nations, Egypt perhaps excepted, earned only their two hundred; but of late years, England with the marvellous growth of its iron industries, America through the discovery of its gold and silver deposits, South Africa with the diamond mines, and Australia with its gold, had thrown the wealth of India into comparative shade. Moreover, the supply by these countries in so large quantities of the metals and other useful mineral products, together with the great advances in navigation, had rendered it possible to offer in the bazaars of India those foreign productions at a cheaper rate than those indigenously produced.

He then proceeded to the inquiry as to what were the actual mineral resources of India. He showed a table which he had prepared, giving a list of 82 useful minerals, and dividing the whole of India into 103 different areas. An easy reference to this table would show in which of those 103 areas any particular one out of the 82 useful minerals occurred, and whether it was present in only mere traces, or in payable quantities, or whether further examination was needed. The information for the preparation of the table had been obtained almost exclusively from the publications of the Indian Geological Survey; and mainly from the third volume of the "Geology of India," published by that department. The useful minerals of India were for the sake of convenience divided by the lecturer into fuels, metals, precious stones, building stones, clays, cements, chemical requirements, manures, and miscellaneous substances. It was impossible in the space of four lectures to undertake a detailed inquiry into the deposits in India of all these minerals: out of 82 of the economic minerals they could give a general glance at only 28. Under the heading of "Fuels," the coal fields of India were touched upon, and it was stated that India contained the thickest known coal seams of the world, some being 100, 120 and 180 feet thick. On the Ranigunge coal field, which had a probable area of 1,000 square miles, there were in 1872 no less than 44 mines at work. In 1879 this field yielded 523,000 tons of coal, and gave employment to 389,000 men, 195,000 women, and 27,000 children. The expense of carriage of coal over land was very considerable and prevented the Indian coal fields from meeting much more than the local demand. Coal which in 1880 sold at 2½ to 3 rupees at the pit's mouth on the Raniganj coal field, cost 7 to 8 rupees in Calcutta and no less than Rs. 50 in Lahore. Mr. Ball, in his little book on the "Diamonds, Coal and Gold of India," stated that the annual consumption of coal in India was upwards of one

and-a-half million tons, and that in round figures two-thirds of this amount was raised in the country. As a sign of progress in the development of Indian industries this statement was not unsatisfactory; but it was completely dwarfed when one turned to the statistics of the English coal fields, where in 1872 not one and-a-half million, but 123½ millions of tons of coal were raised, 16 millions of which were exported, and the rest consumed in the country. Other fuels, such as wood, peat, lignite, and petroleum were dealt with; and before leaving the subject of fuels, the importance of the sun's heat as a fuel was pointed out. However unequally wood and coal were distributed over India, there was no doubt that sunshine was given impartially enough. Some efforts to use it in a concentrated form had been made in the drying of tea but with only partial success. For most chemical processes and even for brick-burning, the lecturer believed a determined effort to apply it would result in success.

Amongst the group of metals, the lecturer touched upon iron, silver and gold. Gold, it would be ascertained by a reference to the aforementioned table, occurred at 41 places out of the 103, and out of these 41 places there were no less than 11, where it has occurred in sufficient quantity to make its mining profitable. There was abundant evidence to show that gold was formerly obtained from these places in large quantities; but there was no evidence, so far as the lecturer was aware, which showed that the miners who obtained these large quantities grew wealthy by their industry. The south of India was, and appeared always to have been, the most important gold region in the country. The river beds all about the region of Malabar were known to contain gold: in many places the inhabitants had traditions of gold having been washed there; some of the rivers and villages were named after the precious metal. These rivers took their rise in the Wynad, the Nilgiris and the neighbouring hills. The occurrence of gold so generally in these rivers did not, however, imply that rich deposits of gold would be found in the mountains whence the rivers sprang; for it should be remembered that the water of the rivers effected a process of concentration, carrying away the lighter particles of mud and sand, and allowing the heavier, amongst which was the gold, to remain behind in the river beds. As a matter of fact it would be found on a sufficient examination that the rivers had got nearly all the gold, and that there was very little of it left in the rocks *in situ*. Most of the reefs in the Wynad were but the ruins of what they once had been. Ages ago, at a period so long back that it must be reckoned not by historic, but by geological time, there could be no doubt that the reefs of the Wynad were extensive enough, and that it was then a gold region of very considerable magnitude. But now there are to be seen, generally speaking, only fragments of this former greatness. The mills and the reefs with them have been washed away by the incessant action of the weather. After a further description of the gold regions, the lecturer went on to say that, as to whether the 44 companies and the four millions of money engaged in the gold adventure in the south of India would or would not produce profitable results, he has no hesitation in saying that as a whole they would not. They could not, and no reasonable man would expect a mania to result in anything but disaster. Taken individually, some few of the companies that had gone cautiously to work might succeed, especially if they had been fortunate enough to find "pay shoots" of fair size and after but a short search. The easily and quickly found "pay shoots," however, namely, those which came up to the surface, had been nearly all worked out years ago by the natives; and it required no illustration to show that the underground search for these might involve an expenditure of considerable time and money, and after all result in nothing but failure. Amongst the precious stones, the localities of occurrence of diamonds, corundum, agates, &c., rubies, sapphire, and lapis lazuli, were mentioned, and some details given as to the nature of the deposits. Amongst the building stones, were specially noticed the granite, slate, and marble. Amongst the clays, pottery clays, more especially Radlin deposit were mentioned; and the necessity for attention to a deposit, of fire-clay pointed out and emphasized. The mineral resources of India could not be developed without furnaces and furnaces could not be built without fire-bricks; yet nearly all the fire-bricks used in India were imported. Amongst cements, the materials for the manufacture of Portland cement and of plaster-of-paris were mentioned, and their occurrence in India pointed out. Amongst the chemical requirements, alum, sodium, carbonates, borax and iron pyrites were noticed. Under the heading of alum the manufacture of Kutch alum was noticed; the process of manufacture was stated to be unique. The lecturer said he had ascertained the deposit of alum earth in that state to be probably extensive enough for the supply of all India with alum for some hundreds of years. The mineral manures were of great importance, and would become more and more so in this country every year.

Having briefly indicated the occurrence of the more important minerals in India, and pointed out where complete information about them could be obtained, attention was then directed to the work of their actual development. Having fixed upon the development of any particular mineral deposit, the first step to be taken was to find out in a general way what might be the extent and average quality of the deposit, and to make sure of a certain definite value of the same before staking a large amount of capital in the undertaking. This process was known in mining language by the term "prospecting," a word which simply meant a looking before hand. Looking beforehand was one of the most important branches of mining engineering, and required no little exercise of knowledge and natural skill to accomplish it successfully. Its importance would be apparent to every one. It was a very old observation that a man going to build a house, "first sitteth down and counteth the cost." Had this matter been more widely understood by intending investors in Indian gold mines, there would have been less capital invested

in those concerns. The lecturer described and illustrated in considerable detail the nature of reefs and of vein deposits generally, and showed the methods of the underground prospecting and actual working of these, illustrating his descriptions throughout by diagrams and drawings on the blackboard. He described the methods of supporting mining excavations by timbering and masonry; and pointed out the special difficulties in this part of mining work in India owing to the softening of the ground by the monsoon rains. He concluded by expressing a hope that the lectures, necessarily of a somewhat general and outline character, might stimulate some of the natives of the country to look upon mining work as affording a useful and suitable career for a man throughout life. Such work had frequently been regarded as of an inferior kind. This idea had doubtless originated from the characters of several men who had entered into it. Being necessarily a work considerably of chance it had attracted men of a gambling turn of mind, who had done not a little to injure the reputation of the industry. But he thought that when all was considered which had been brought forward in the lectures, it would be perceived that mining work was properly of a most honorable character, presenting as it did problems which called forth for their solution the best natural abilities and acquired attainments.

At the end of the fourth lecture, the chairman, Mr. Words, the Consulting Engineer to the Municipality and President of the Season Mechanics Institute, said that he was sorry to have to announce that this was the last of Mr. Pearson's very interesting and able lectures; and he was sure they would accord a hearty vote of thanks to him for the trouble he had taken in their preparation and delivery. Mr. Pearson, in reply, stated that it had given him great pleasure to be associated with anything useful; but that he had been greatly encouraged in his by-no-means easy task by the constant attention with which the lectures had been listened to. — *Times of India*.

THE AGRICULTURAL EXHIBITION.

I.

THE agricultural exhibition which has recently been held on the island has deservedly attracted a large amount of attention; and, it is to be hoped, will be productive of as good results as similar gatherings have been found to lead to in America and England. Nine years ago a similar exhibition was held, as some of our readers may remember, at Saidapet, and it was originally intended that there should be an annual one. Various reasons led to the Government postponing the idea, the famine being one of the chief; and it was not until last year that Mr. Robertson was able to persuade Government that the time had come for taking a new departure in this respect. It has now, we believe, been decided that a general central exhibition shall be held in Madras quinquennially, or septennially, and that, in the intervening years, district shows of a similar nature, but on a smaller scale, shall be held annually in various selected localities. This, we think, is likely to lead to better results than, as seems to be the wish of some, would arise from holding annual exhibitions in Madras itself. The only fear is that the experience gained in the present case may be lost, and various errors and defects, which we shall notice hereafter, may occur, and in a great measure lessen the value which should be attendant on a well-devised and managed exhibition. Such gatherings as we have recently witnessed, to be of full value, should be arranged so that not the slightest hitch should occur; and there should be no difficulty in making out what the exhibits are, and whence they came; for their greatest value lies in keeping the public informed of where they can obtain what is brought before them at the exhibition, and the probable prices of such articles.

In the section of the show directed to live-stock, we have not much to complain of, but we must remark that we fail to see the utility, apart from its adding to the attractiveness of the show to visitors, of any money being spent by Government in trying to get together any number of horses. Horses, as is well-known, play no part in the agriculture of Southern India; they are neither used in farming operations, nor are they bred for sale. It seems to follow, therefore, that the money offered as prizes for them at the recent exhibition might, on another occasion, be much better spent in rendering other portions of the exhibition more complete. Amongst the cattle we have only one thing to complain of, and that was the difficulty in distinguishing which animals were competing for particular prizes. Practically, the only cattle shown were Nellores, for the other stock were but a poor show, and it is most regrettable that no Mysore cattle were brought forward. We have in this Presidency in reality only two good breeds of cattle, the Nellores and the Mysore, and each type fills a different place: the former are a large, heavy-framed, powerful breed, producing good draught animals for slow work which requires great strength; the latter are light, strongly built, and active animals, very suitable for the ordinary operations of farming and road-work. The Nellores have the additional advantage of being fair milkers, and therefore more generally valuable to the native; but they are too large and heavy for use in crossing on the small, degenerate, breeds of the Southern districts, with a view to their improvement. The Nellores at the exhibition made really a splendid show, and the two magnificent old bulls, brought down by their owners from near Ongole simply for show, were as fine specimens of the breed as any one could have wished for. As might be expected, however, showed the defects of the breed, a heavy, languid appearance,

want of birth in the chest, although in depth of carcass, they were not specially deficient. Amongst the younger bulls, both yearlings and those under three years old, the tendency which the breed has to run to leg was much more marked, and showed that in one respect at least the breed is capable of great improvement, and that in its early development. In three years it should be possible, where it is feasible to raise such stock at all, to turn them out nearly fully developed; but it would appear that the Nellores do not reach their full development until five or six years old, or later. Amongst the cows of this breed there were shown some remarkably fine animals, but we could not understand some of the awards; some animals were apparently passed over without cause, and inferior ones placed above them; in particular, we could not agree with the judges in the award to the old cows, for the fourth prize cow appeared to us as fine as the winner of the first prize, and much superior to those placed second and third, whilst another particularly fine cow was left out entirely. As long as the judging is placed in the hands of amateurs, who have had few chances of acquiring the special skill necessary to adjudicate on the different points of cattle, the results of their awards must necessarily be open to criticism; but we fail to see why it should be impossible to find qualified judges for the work. Surely a district which can produce such cattle as it was our pleasure to see assembled last week, can also furnish competent judges. To the holders of this breed the same remarks, as we have already made with reference to the young bulls, equally apply; but there was not the same uniformity, in colour at least, displayed, indicating perhaps that some not pure bred animals had got in.

Of working cattle, whether for heavy or coach work, the show was very poor, and this is in a measure surprising, as it would appear likely to have been a profitable undertaking for the breeders to bring down animals of this sort, for which we imagine there is a ready demand. As it was, the only pair (and a fine pair) of heavy draught cattle came from Arcot, where they could not have been bred, and even these would not have compared favourably by the side of such magnificent draught cattle as we have seen in the Ceded Districts. At present, heavy draught cattle are only bred in Nellore, and the chief market is in the districts named, the cattle being taken over annually by the dealers and dispersed by them over the country. The light draught cattle were a better show in point of numbers, but not in quality, and the show was really poor in quantity, considering how much larger a stock of this type of animal there is. We saw no representatives of the draught bullocks of Coimbatore and Salem, nor any of the true Amruti Malial type in its best form, those shown having something of the latter type, but appearing under-bred. This latter type of animal is specially adapted for improving both the form and size of the diminutive Carnatic cattle, as being intermediate between the latter and the heavy-built Nellores. One very interesting exhibit we did notice in this section of five young bulls of the Aden breed, imported by Government last year, with the object of furnishing sires of a good milking strain for use in the districts, the experience gained at the Saidapet farm with a bull and cow imported in 1874 having conclusively proved the value of the breed in this respect. Besides their good milking qualities, the breed is remarkable for its docility, and at the same time the animals are of fair size and form, and intended to improve the ordinary ryots' stock considerably. It is only to be regretted that 500 instead of five such young bulls could not be supplied for use in a selected locality; but we must remark that until all other stock-getting animals are removed, or their powers destroyed, no really good results can be expected to follow from the use of five or of five-hundred sires of good breed. The remainder of the cattle were not worthy of much attention, and, though in some cases evidencing great spirit of enterprise on the part of their owners, did not show favorably beside the great gathering of Nellores. One cow only do we feel specially called on to refer to, and that was a brute shown by a gentleman in Madras, to which the judges awarded a special prize—why, we cannot understand. In a milch cow docility is of primary importance, and a more dangerous and vicious beast than this one we have seldom seen: in form the cow had several good points, but her temper was enough to cancel them all, and the only thing she appeared fit for was the butcher.

The show of sheep was poor, and here the chief exhibitors were Europeans. The cattle were chiefly brought down by native breeders for the show simply, as they refused to sell many of their animals. Of course persuasion may have been freely used by the district officers to induce the cattle-breeders to come down with their stock, but nevertheless it is disappointing that, in a province containing some four million sheep of several distinct and well marked breeds, so poor a display should be made. There is, we believe, no reason why India should not equal Queensland in wool growing; we have good stock to begin on, which, if small, is hardy and covered with wool, which only requires judicious crossing and selection to be improved greatly and rapidly. The small exhibit (for show only) from the Saidapet farm was interesting as showing the results of selection in breeding, but it only brings home to our mind the pothering manner in which this great subject has been taken up in India. We hope for better things ere long, but Government ought to be in a position to supply every flock-master in the country, who can be induced to take them, to the exclusion of rams of his own breeding, with sires for breeding of a good, thoroughly acclimatised hardy, wool-bearing type of sheep. The show of goats was small, although there were some interesting exhibits, but that of poultry was full, and was interesting as showing that the natives are, to a certain degree, taking to keeping fowls of good breeds, a good number of the prize-winners being natives. On the whole, the exhibition of live-stock was successful, but it will be well, on another occasion, to endeavour to get together more working cattle, sheep, and particularly representatives of the Mysore breed. Our remarks on the arrangements of the Exhibition we shall reserve for another occasion, when we have had an opportunity of referring to the dead-stock exhibits. —*Madras Mail.*

II

TURNING now to the dead-stock exhibits, and first to the implements, machines, and tools, we must remark that, as a whole, the display was not gratifying. Though large prizes were offered for fibre-cleaning, oil-pressing, and paddy-husking machines, none were awarded, and it is much to be regretted that these prizes did not induce any manufacturers to come forward. Machines for the two first purposes are very much required, and though a Boomer oil-press was exhibited by itself, it is of little use, as the oil-seeds require to be crushed or bruised before pressure. Considering the extremely inefficient extraction made by the native oil-mills, and the large proportion of oil left in the refuse cakes after pressing, it is surprising that attention has not been more strongly drawn to the opening that exists for the introduction of complete and efficient oil-mills and presses into India. In the interests of the country agriculturally, it would be well worth while for the State to offer considerable inducements to any one who will introduce and work such presses as will prevent the seeds from being exported as now; for if the most valuable portion, the oil only, is sent to Europe, the country, that is, the soil, will lose little by the growth of oil-seed crops; but whilst the seeds still continue to be sent home, a continual and heavy drain is made thereon, while there is no corresponding import of manurial substances to balance. In fibre mills, again, there is a great want, and though the large prizes offered by the Government of India for the production of a machine capable of cleaning the rhea fibre have hitherto been without satisfactory results, there is also a great want of a machine capable of dealing with such plants as the aloe, the common plantain, and the manilla hemp, all of which contain strong useful fibres, but which cannot be extracted economically by hand. The hand-mortar for cleaning paddy, to which a prize was awarded, was only an ordinary native mortar, but of rather superior finish. It was, we believe, exhibited without its pestle! The only cotton-gin shown received a prize, and was one of the well-known pattern of Burgess and Key's emery's saw-gins, which have so long occupied a foremost position in gins of that type. Some native roller-gins were exhibited, but none possessing any better character than those in general use. The three patterns of Messrs. Thomson and Mylne's Behoon sugar mills, exhibited by Messrs. Oakes and Co., deservedly attracted attention both for their hardness and efficiency, of which any one could judge, for they were shown outside the yard at work. This mill has been a great success in Northern India, and the first brought to this Presidency about two and a-half years ago, after being tried at Saidapet, was forwarded for more complete trial to Bellary, and there compared well with the local mills, although far from being so superior to them as it is claimed to be over the indigenous mill of Bengal and the N.W. Provinces. Since then, we learn that another of these mills has been sent to Bellary, quite recently, this time a three-roller mill (the first having only two rollers), and this has been much more successful. A mill of this last pattern was at work in the showyard, as well as a two-roller mill. Deservedly these mills obtained prizes, for they are portable and easily set up, and more efficient than the native wooden mill; whilst their price is nearly the same, and the materials of which they are made much more durable. When the wooden frame-works are made up locally, and the iron works only purchased from the manufacturer, the price of these mills should be reduced to a point considerably below that of the native mills. Messrs. Oakes, who exhibited these sugar mills, also obtained a prize for a winnowing machine made for them in England; but we think the machine is much too heavy and costly to be likely to meet with general favour in this part of India.

The most interesting part of the exhibition in this section was the comparatively large show of ploughs. For this Sweden, America and England all contributed, besides local manufacturers in Messrs. Massey and Co., and the Sangal Works at Saidapet. The judges apparently were unable to follow the classification of prizes offered by the Committee, and awarded prizes for ploughs, not according to the materials of construction, but according to the purposes for which the various ploughs were adapted. In this we think they were right, for the efficiency of ploughs can be more fairly compared in this way, it being manifestly impossible in any way to contrast the value of a "wood-plough with iron working parts," intended for breaking up black cotton soil to a depth of 12in., by means of four or five pair of large Nellore cattle, and one of similar materials designed to replace the crooked stick of the ordinary ryot, and to be used with his diminutive stock. Three classes were formed: one for heavy ploughs suitable for deep work, row performed by the ryot of the Ceded Districts, when reclaiming foul land, with his *pedda mudaga* (one of which we saw in the exhibition); another for strong ploughs capable of doing all the ordinary operations of cultivation; and a third for light ploughs of low cost, which, though fairly efficient for general purposes, were specially designed to be made at a price within the means of the great bulk of our ryots. In the first division the show was good, but almost the sole contributor was Mr. Sabapathy Moodelliar of Bellary, who, besides three ploughs which the judges considered worthy of consideration, exhibited two English multiple-furrow ploughs, which he is using in Bellary. Besides the above-named gentleman, the Sangal Works exhibited a plough made on the lines of one imported by the Agricultural Department some years since from Sweden. The latter obtained the second prize, the first going to one of slightly different construction imported from Sweden, to the exclusion of either of the very useful looking ploughs made by Messrs. Collins, United States. In the second division, or ploughs of medium size suitable for general purposes, the competition lay between exhibited by the well-known firm of Ransomes, Head and Jefferies, of Ipswich, and a plough made by the Oronum Bank, Sweden, of which a large number have recently been imported by the Agricultural Department for distri-

bution and sale throughout the presidency, and are made up by Messrs. Massey and Co., locally, something on the lines of the Swedish plough, but with considerable alterations. The first prize went to one of Ransomes' ploughs bearing their mark K.W.S., a very useful, light, and strongly built plough, costing Rs. 18-8, with steel-bearing parts and a wheel. The second prize was awarded to Messrs. Massey's plough, which, though built on good lines, had a considerable objection in that castings were made use of in it; its price with castings was Rs. 15, but made in wrought iron Rs. 18; and when made in the latter material, it should be a most valuable implement. The Swedish plough favored by the Agricultural Department was excluded apparently because of its weight, but at the price at which it can be delivered in Madras, Rs. 18, it is a wonderfully cheap, useful, and strong plough. In this case, as in that of other implements, we must remark that we cannot regard the awards as at all final, for, with ploughs especially, it is impossible to fairly judge their qualities without trial in the field, and with a dynamometer, besides having regard to their construction, the materials used, and the cost. On another occasion we trust that all the ploughs at least will be put through and through practical trial before the prizes are awarded; the exhibition will then be of much greater educational, or rather instructive, value to the visitors; and seeing the necessity that exists for Government to find out whence the best and cheapest (not lowest priced) ploughs can be obtained, we hope that the Exhibition Committee will recommend that all the exhibits considered worthy by the judges may be put through an exhaustive series of practical trials under various conditions in different localities. We have no quarrel to make with the award given, but we think the judges will admit that these awards were made on insufficient data; that a few hundreds of rupees spent in the way we mention would be productive of much good, we feel assured. Let it be advertised that the practical plough trials will be held in Bellary, at Saldapet, and in Tanjore, for instance, in July or August next, and let arrangements be made for the full trial of all such ploughs as are brought forward, and we shall then be well able to repose confidence in the verdict. In the third division of ploughs, that is, those of very light construction and low price, the judges divided the prizes between a small wood and steel plough made by Ransomes and an iron plough made by Massey and Co., both costing Rs. 10. In the latter the body, share and mould-board were all castings, and the two last portions being cast in one piece would have to be replaced together, though in practice five or six shares are worn out to one mould-board; this difficulty the manufacturer has, we believe, got over at a slightly increased cost; but the use of castings at all in implements to be placed in the hands of ignorant ryots we look upon as inadvisable, as an unfortunate accident might lead to the plough being thrown aside, and the whole tribe of which it is a type brought into disrepute.

We have entered so fully into the question of ploughs, that we have little space left for remarks on the other exhibits; but we regard the question of providing a good, cheap, and efficient plough of so great importance, and that of all other field implements at present of such secondary interest, that we believe ourselves justified in doing so. No suitable cultivator or grubber was shown for competition, although a second prize was awarded to one of Messrs. Coleman and Morton's make; but we observed one amongst an interesting collection of exhibits sent by the Saldapet Farm of very simple construction. In this place we must remark that we regard the rule preventing Government institutions from competing for prizes as a mistake. They should be allowed to compete, as they can often show the best and most suitable exhibits; and as these exhibitions are so valuable for instruction as for anything, the best exhibits should obtain the prize. It would be easy to arrange matters so that no money should be paid to Government institutions. Just as in the grubbers, so in the harrows; the one most suitable to the wants of the country was exhibited by the Saldapet Farm, but no attention was drawn to it by its being awarded a prize. The iron harrows by Howard of Bedford, shown by Sahapathy Moodelliar, for which a first prize was given, appeared to us much too heavy for general purposes.

Of the other articles shown, there is not much to be said. Both Messrs. Oakes and Messrs. Massey showed interesting collections of useful tools, and the former a collection of useful dairy utensils; whilst the latter were deservedly awarded a special prize for one of their well-known coffee-pulpers. Nothing new was brought out in the way of water-lifts, but the wind-mill working in the grounds attracted considerable attention, and we frequently heard the oft-repeated remark that wind-mills had not been sufficiently tried in India. Hitherto all the trials that have been made have been unsuccessful, and we do not hope for much from them in the future. In this department of the exhibition, as in all others, the same want of knowledge of what was being shown was patent to all, and we think that on another occasion some attempt at a catalogue should be made, at least of those articles competing for prizes. We hope to be able to refer to the raw products and manufactures exhibited at an early date, when we shall have something to say also on the general arrangements of the exhibition.—*Madras Mail*.

III.

WE have now come to the most difficult portion of our task, for it was in the portion of the Show devoted to raw produce that the arrangements were most defective, and where it was most difficult to discover what was what. The confusion which existed was, we believe, for the most part due to the hurry with which everything was laid out for exhibition, and also, in a great measure, to the exhibits being forwarded to the Secretary often without

lists, and generally with no one in charge to see that the exhibits were laid out in a suitable manner. Consequently the whole work of laying out and arranging them as far as possible practically devolved on the Steward in special charge, on whose shoulders also fell, in addition, the same duty as regards the exhibits of manufactures. It was a simple impossibility for any one person to get into anything like proper order such a number of exhibits delivered in the state mentioned. About 3,000 exhibits were, we believe, sent in, and often a single exhibit consisted of many different articles, so that at least 5,000 or more articles had to be dealt with in the short time allotted—three days only! It is surprising that so much order was actually attained, and that greater confusion was not visible to the casual visitor; but we hope that on another occasion the Committee of Management will anticipate the difficulty, and provide adequate means for laying out and displaying the exhibits in such a manner that the public may derive the fullest benefit from the Show. As it is probable that some years may elapse before another such exhibition is held in our city, we trust that the opinions of those Stewards of sections who did actually discharge the active duties of their office, will be asked for and recorded for the guidance of future committees, which must, from the shifting nature of our population, on a future occasion, consist almost entirely of new men, who will be altogether ignorant of the difficulties met with on the present occasion; and we also trust that when another exhibition is held the Stewards generally will have learnt better how to discharge the responsibilities which they have undertaken. The Stewards in each section of an exhibition should be practically a working Sub-Committee, and see that everything is arranged to the best advantage for display and instruction to the public, and should have such a knowledge of what is exhibited as to be able to direct the work of the judges, so as to save the labour and time. They will only be able to do this by insisting that all exhibits should be delivered in a proper state for exhibition at least a week or ten days before the Show is opened to the public, and so marked that no confusion can possibly arise, or the exhibits be placed in sections where they are altogether out of place. In a great measure the Stewards must depend on the exhibitors for facilitating the accomplishment of these ends, and with every exhibition the exhibitors will learn better how to prepare and send up their exhibits. In an initial undertaking like that recently held, of course a great deal must be in a rudimentary stage, and, considering all things, we must allow that a great deal of success was attained.

In the judging, too, we saw much still to be desired; the selection of competent judges ought to receive more attention, and the work should be more sub-divided; the judging should be done before the public are admitted; we can see no reason why the names of the exhibitors should not be attached to all the articles; and we regard it as essential that the cost of manufactured articles, as well as that of partially prepared produce, such as fibres, should in every case be stated and considered by the judges. In the selection of the judges, we think it must be evident to all that specialists should be selected; a man, who is a good judge of grains and fodders, is not necessarily a good one of fibres. In another matter also the Committee might improve matters, and that is in the simplification of the prize lists. Unless the exhibition is to be of a more permanent character in future, the offer of separate prizes for a long list of varieties of grains and pulses seems to us inadvisable, and the offer might well be confined to collections of the common grains with a few prizes for special new products, which it is desirable to encourage; paddy, however, should always be kept separate from the unirrigated grains. We should, nevertheless, look upon the establishment of a more permanent exhibition with favour. In a Show like the recent one, it was almost impossible for any one, with the amount of leisure usually at the disposal of most people in this country, to form a fair idea of the exhibits of any particular description of produce, it would be much more beneficial to the country if the exhibits of produce could be kept on show for several weeks, and thus afford ample opportunities to those interested to study them at their leisure. In the exhibits of grains and pulses, the visitor was brought face to face with the fact that the natives recognise a tremendous number of varieties of paddy; one collection from Malabar consisted of 116 samples, and to render the subject more confusing, the names of the different sorts vary in different localities, so that it may almost be said that the names of varieties of paddy are legion. The Committee attempted to classify all the varieties of paddy under the heads Kar and Samba—divisions well known in some parts, but altogether unknown in others of the Presidency. The show of paddy, as a whole, was disappointing; partly from the confusion, partly from the want of names, and a good deal from defective arrangements. Prizes were offered for samples of the Carolina and Madagascar varieties, but although we noticed that the judges had awarded prizes for them, we were unable to find them. The collections of various descriptions of unirrigated cereals were particularly fine and deserved great attention, but there also the want of adequate arrangements prevented the visitor from finding out whence the prize samples had come, and we believe that it was not until the close of the exhibition that the names of the owners were all found. It is doubtless convenient to give each exhibit a number, but a label bearing the mark "Exhibit No. 1,000, Div. (a), Class 1, Section B," does not tell much to those who come to see and learn! In the pulses, the same excellence of samples was visible, and we really can scarcely understand how the judges were able to discharge their work. On another occasion, it will be better that, at least with some grains, the sample should be accompanied by a sheaf of corn in the straw. The oilseeds also came out strongly, but nothing new was exhibited on a large scale. Tinnevely alone coming forward with a good collection of miscellaneous oilseeds, but in that case the quantity of each sort was very small. The exhibits of cotton were good, but it was not possible to see them to advantage, and before another

These figures show how carefully deduction must be made from the results of experiments, as a more propitious season than usual may lead to results which appear contradictory, and also how long experiments, of the description of those above referred to, must be continued before absolute results can be at all arrived at by averaging the returns of a number of years together. They should, however, be very valuable in convincing any one who is still sceptical of the fact, that Indian soils are in a very exhausted condition, for the latter are almost continuously cropped with corn of some description. A good deal might be done on Government Experimental Farms in India, in collecting data of a similar nature to those given above, and a commencement has been made already in that direction at Saidapet.

Another very remarkable set of results, of great interest to those connected with Indian agriculture, are those obtained in the growth of wheat alternated with fallow and wheat grown continuously on the same land in adjoining plots. They are given below :—

| | TOTAL CORN, LB. | | | | STRAW, LB. | | | |
|------------------------------|-----------------|---------------|---------------------|-----------------------------------|---------------|---------------|---------------------|-----------------------------------|
| | After fallow. | | Grown continuously. | | After fallow. | | Grown continuously. | |
| | Produce. | Half-produce. | Produce. | + or - half-produce after fallow. | Produce. | Half-produce. | Produce. | + or - half-produce after fallow. |
| Five years 1856—60 .. | 1,598 | 799 | 1,013 | +218 | 2,014 | 1,257 | 1,088 | +491 |
| Do. 1861—65 .. | 1,608 | 804 | 953 | +149 | 2,438 | 1,216 | 1,390 | +174 |
| Do. 1866—70 .. | 996 | 498 | 834 | +360 | 1,394 | 697 | 1,122 | +425 |
| Do. 1871—75 .. | 786 | 393 | 656 | +268 | 1,430 | 710 | 1,031 | +312 |
| Do. 1876—80 .. | 754 | 377 | 567 | +190 | 1,149 | 575 | 877 | +302 |
| Twenty-five years 1856—80 .. | 1,186 | 593 | 804 | +236 | 1,786 | 893 | 1,221 | +338 |
| 1881 .. | 748 | 374 | 369 | +499 | 897 | 449 | 1,146 | +607 |

The figures showed that over a period of 25 years half the biennial produce (i.e., the average annual produce) of the land alternately fallowed and cropped has been 236 lbs. or 31 bushels of corn, and 328 lbs. of straw less than that obtained from the adjoining land continuously cropped with wheat. The figures for the crops of 1881 are also remarkable, and the whole series show the exhausting effect of continuous corn-cropping without manure, and still more so of alternate fallows; they also show how great is the effect of season on the outturn. The main results can be explained by the fact that the drainage through fallowed land carries off more nitrogen from the soil than that from cropped land. They show that though a bare fallow may be advantageous by allowing, through a temporary cessation of cropping, the soil to accumulate larger immediately available supplies of nitrogen (for other purposes) if the practice be continued, it is really more exhausting than continuous corn-cropping. These results ought to be remembered in India, where fallowing is generally looked upon as a most valuable preventive of exhaustion; but there the danger is not so great as the loss from drainage would never be so much, as the native cultivator never bare fallows his land in the manner done in England; he allows it rest from cropping, but does nothing at the same time to prevent the growth of weeds over the surface, or to open up the soil, so that it may be thoroughly aerated. The weeds in their growth prevent a considerable amount of loss by drainage.

It would be most beneficial if experiments similar to the above were carefully conducted on all Indian Experimental Farms.

The rain and drain gauges used, and the system of observing the results obtained, are also well worthy of adoption on Indian Experimental Farms, as very valuable data could be collected by that means. They are fully described in the Journal of the R. A. S. C., Part I of 1881.

The above are the chief results, &c., which I noticed at Rothamstead that are of most interest in India; but the care with which the soils are sampled frequently for analysis, the grasses from the continuously manured grass-land are collected, sorted, and the effects of the different manures on the herbage tabulated, and the work always going on the laboratory in analysing the soils and samples of the crops grown, are most striking.

With reference to one problem which has received a great amount of attention, and which is still a point of controversy

amongst agricultural chemists, viz., the sources of the supply of nitrogen to plants, Dr. Gilbert requested co-operation from the department to which I belong, and especially asked that he might be furnished from Saidapet with the following information:—Statistics of produce of leguminosae on sandy soils. With information, if possible, of the average percentage of nitrogen in the dry matter: how frequently the crop can be grown, and whether it leaves the land in an exhausted or improved condition for other crops (cereals, &c.); stating how the crop is dealt with, removed, ploughed in, or fed off, and he added that "it would be very desirable if careful samples of the soil could be taken to every 6 inches to 4 or 5 such depths, and the nitrogen determined in the land before sowing the leguminous crop, and also after its growth and removal; it being essential to have the samples from a fixed area and depth. Four, five or six samples should be taken from each plot or field at each depth. Of the surface samples half of each should be kept separate, and the other halves mixed; of the subsoils a mixture may be made of all of the samples from the same depth in each case; the reason for retaining half of the surface samples unmixed being for reference in case a suspicion that any one contained the droppings of some animal arose. The weight of the soil samples should be taken in the field; afterwards they should be sifted successively through sieves of 1 inch, $\frac{1}{2}$ inch and $\frac{1}{4}$ inch mesh, and the weights determined in each case and calculated back to the original; what last passes through call 'mould.' Then determine the dry matter in the mould at 100° C after powdering finely and calculate back to the original 'weight.' Although the above data have been asked for with special reference to the Saidapet farm, if similar figures could be obtained from other parts of India and on different soils, they would be most valuable in assisting in the solution of the problem I have already referred to.

On his farm at Sawbridgeworth, Mr. Prout has been growing corn continuously over nearly its whole area for nearly 20 years without intermission, and the crops he now grows are very heavy and show no signs of diminution. The system which has enabled him to do this is deep and thorough cultivation (by steam) combined with an extensive use of artificial manures, e.g., a very fine crop of barley which I saw, had been manured with artificials to the value of £2-5-0 per acre. No stock is kept except a few horses for carting, &c., and one cow for dairy; this condition is very similar to that of the Indian ryot, who in general only keeps stock for draught purposes. Mr. Prout's results show that continuous corn-growing may be made remunerative and not injurious to the land, where a supply of artificial manures is available and is properly used; they are also interesting as being a practical application on a large scale of the teachings of the Rothamstead experimental plots. The system can never be fully followed by the Indian ryot, for he will never, as far as we know or can foresee now, be able to obtain a supply of artificials at a price which the market value of his crops will enable him to give; but in one respect he may well be urged to follow Mr. Prout, and that is, in deep and thorough cultivation; and if he did so, the results would be most beneficial to himself and to his landlord—the Government.

SINCE the last special report on operations of the Agri-Horticultural Society of Madras, furnished to Government under date 27th November 1878, this Society has not relaxed its efforts to perform its self-imposed public work, and to confer such benefits on the public as lie within its sphere, those efforts being, however, often cramped by the necessity for husbanding its resources.

During the time referred to, the Society has introduced, experimented with, or distributed, in addition to curious and ornamental plants, large numbers of valuable trees, plants and vegetables of known economic value, particularly Persian Date Palms, the Copal Varnish Tree, African Oil Palm, Mahogany, Landolphia, Ceara Rubber, Carobs, Brazil Nuts, Sapacia Nuts, Queensland Nuts, Water Chestnuts, Cocoa, Chinchona, Cloves, Nutmegs, Liberian Coffee, Bhamie Cotton, plants for fibre and paper-making, Eucalypti, and grasses and fodder plants.

Ploughs, scythes, galvanised wire, canvas and rubber hose for irrigation, pumps, syringes, and other agricultural and

horticultural implements have been imported, or obtained, and distributed to various places in India and Burmah.

Gardeners have been engaged and sent to employers in India and Burmah; and many boys are constantly being trained in the gardens.

The already magnificent botanical collection belonging to the Society is being almost daily added to, and a new Botanical Garden has been laid out and maintained.

A very extensive correspondence on botanical, arboricultural, agricultural and horticultural subjects has been kept up for the purpose of diffusing information; and the monthly Proceedings of the Committee have been regularly printed and distributed to members of the society, other similar bodies, and to persons interested in the various subjects to which they refer.

Publications on economic plants and their culture, and catalogues of plants and garden and other requisites have been obtained from, or voluntarily sent by, the publishers and added to the Society's library (which, though limited, forms a much used source of information on arboricultural, agricultural, and horticultural subjects), or sent to persons requiring them.

Botanical specimens are given freely, whenever asked, to local professors and lecturers, and scientific visitors, and the Botanic Garden is believed to be of great service to the students of the various botanical classes.

The Society acts, and is largely employed, as an agency through which persons at a distance obtain supplies of fruit, avenue shade, and other trees, plants and seeds, and annually obtains and forwards to all parts of India, and often abroad, large quantities of grafted mango and other trees, and seeds of many useful plants, particularly *Inga Dnlcis*, *Casuarina*, Cotton, Tobacco, Senna, Forage-plants, and Maize, and other cereals.

The Society is often honored by references from Government and the Board of Revenue for information on horticultural and kindred subjects; and is frequently able to be of use to Commissioners, Collectors, and other authorities in distant provinces.

The increasing interest of the natives in the objects of the Society, and their marked success in imitating its European supporters, may be gathered from the number of prizes won by them at the Society's Annual Shows, as detailed in the lists annexed to the Annual Reports; while the sale-books show that if the natives do not join the Society as members in such numbers as is desirable, they contribute handsomely to its support by being large purchasers of seeds, plants, &c.

It will be observed that the Society has no grant from Local or Municipal Funds, and that Rs. 500 out of the Rs. 3,500 annually received from Government is a special grant dedicated by Government to prizes for useful products. The Committee has reason to believe that the Society's medals offered from this fund are much coveted by planters and manufacturers, and observes that success in obtaining them is frequently advertised as a proof of excellence.

BARLEY CULTIVATION FOR INDIA.

(Communicated)

(Continued from page 91.)

CLIMATE.

BARLEY will flourish best in a temperate climate; but being hardy and having various species and a large number of varieties scattered throughout the world, it will grow in wide ranges of temperature. The frost of Indian plains does no injury whatever to the indigenous varieties, much less to barleys of the colder regions. The Indian plains and the hills are admirably suited to barleys of all varieties and of all parts of the world.

TIME OF SOWING.

The same as for wheat—*J. A.*, Vol. VII., No. 4, p. 116. I might as well note here, that the native cultivators of Upper India sow barley from the middle of October to the middle of November.

GEOGRAPHICAL DISTRIBUTION.

The genus *Hordeum* is a native of Asia, extending from the Caucasus mountains all along the east coast of the Mediterranean

Sea down to the extreme south of Arabia, in the west side of Asia to China and India in the east, stretching northward to Siberia. The African barleys originally came from Arabia, and its northern neighbour, Palestine. From some centuries back by means of extensive cultivation and botanical researches, the most approved species with their varieties, have been introduced into various countries of Europe, America, Africa, and even the inhabited parts of Australia. It is, indeed, very surprising to find India has introduced none of the varieties of barley other than what it has from days of yore. I experimented with some of the most approved varieties of the two-rowed, four-rowed, and six-rowed barleys imported from Europe, Africa, Arabia, America, and the Indian indigenous, which succeeded well in the sandy soil and variable climate of Lucknow and Sitapore, and altogether well on rich soil artificially made at these places, from which I believe all exotic barleys, from other parts of the world, will grow remarkably well in India extending, from the hot plains, upwards to 15,000 feet in the Himalayan mountains.

SOIL.

Ordinary agriculturists, on account of their finding barley growing and yielding a fair crop (according to their estimation of fair crop) on poor sandy soil, on which wheat and many other crops would fail, pronounce barley to require a poor soil, much sand, little clay, little or no manurial ingredients, and so forth. This is on account of the sturdiness of barley which certainly deserves better treatment. I have grown barley, and grown it experimentally, I might emphatically say, more than any one, past or present, in India; and from all the data I have gathered about the appropriate soil for this very valuable and badly treated plant from personal experience, can testify that barley requires, if a bumper and nutritious crop be the object, very rich soil—the same as wheat, barley differing from this best of cereal grain plants in this, that wheat will not grow and yield without the nitrates present in the soil, whereas barley will, because barley draws nitrogen from both the atmospheric air by its upper axis and from the soil by its lower axis—i.e., by means of its root fibrils, wheat drawing nitrogen by means of its root fibrils only. Should, however, nitrates be present in the soil, barley will be grateful and repay by yielding a still greater bumper crop. Loamy soil of the calcareous order, and of the species having less lime and more humus.

Composition of soil :—

CHEMICO-PHYSIOLOGICAL REMARKS.

Had it not been for the pretty thick husk or skin adhering to the seed, barley grain would have the smallest percentage of mineral matter not exceeding one per cent; including the husk it has 2.48 per cent, the stem, &c., having 4.99 per cent of it. Of the organic matter the grain has 97.58 per cent; and the stem, &c., 95.01 per cent. Small as these percentages of the ash might appear, the quantity of it carried off the acre is quite large, equal to a cart-load which can only be drawn by a pair of very strong bullocks. This quantity of the mineral constituents of the barley plant must be present in the soil of one acre, and in a form the root-fibrils will imbibe them. If these precautions be not observed in barley cultivation, the cultivator can never hope to crop a bumper crop for which he is always trying. It might also be noted that the barley plant (equally applicable to all other plants), draws a good portion of its organic constituents from the atmospheric air, but the remaining portion must be present in the soil without which the plant will not grow; because this plant draws its food by means of the upper axis as well as by means of the lower axis. These points respecting barley and several other plants have been thoroughly established beyond dispute, by innumerable chemico-physiological experimental demonstrations.

Barley is pretty rich in the metal potassium—as an oxide, the seed has 21.14 per cent, and the stem, &c., 11.22 per cent, of this metal; and as a chloride, the seed has 5.65 per cent, but there is not a particle of chlorine in the stem, &c. The metal sodium is found in combination with chlorine—seed 1.01 per cent, and the stem, &c., 2.14 per cent—a very small percentage: no oxide of this metal is found in this plant. Barley seed is very poor in lime, the stem having more of it for building of its tissues in combination with other elementary substances, seed 1.65 per cent; and stem, &c., 5.79 per cent. Magnesia is more abundant than lime, in this plant; seed, 7.26 per cent; stem, &c., 2.70 per cent. It is remarkable to find so much as 2.13 per cent in the seed, and 1.36 per cent in the stem, &c., of iron, in combination with oxygen, present in barley. Barley is very rich in phosphoric acid, which in quantity ranks second of all elements found in the ash of this plant, silica ranking first—28.57 per cent, and stem, &c., 7.20 per cent. There is more sulphuric acid in the seed than chloride of sodium, but less in the stem—seed 1.01 per cent; stem, &c., 1.09 per cent. Of silica the grain has 30.68 per cent; and the stem, &c., 68.50 per cent. The abundance of silica and potash in the grain is on account of the thick husk adhering the kernel.

Barley belongs to the *silica* order.

STARCH, GLUTEN, AND MALT PRINCIPLES IN THE BARLEY PLANT

A knowledge of the intrinsic value of a plant is essentially necessary for a cultivator beforehand, because such a knowledge will be his guide in the sale of his produce, and he will know what kind of reception his produce will find at the hands of the purchasers and consumers: also he will be in a position not to be duped and overreached by them. To experimenter this knowledge is essentially necessary to enable him to judge of the results of his experiments, i.e., whether he has succeeded or failed to improve the plant he has cultivated. The quantity is nothing, for if it were so, grass would have vied with grapes, all success lying in quality. The native cultivators, as a rule, do not pay attention to the quality of their produce, hence the extensive degeneration found in the vegetable kingdom (cultivated) in India. Brooding over this matter, I think a concise account of the organic principles found in the barley grain (the most important part of the plant) will be found useful and interesting, having already given a detailed account of the ash constituents of this plant. I accordingly proceed to give an account of what I have herein mooted.

The kernel of barley grain, like that of wheat, has two organic substances, having small percentages of mineral matter, known to chemists by the name of *starch* and *gluten*; and when a chemical reaction is produced on them in the process called *malting*, other substances are formed denominated *malt principles*. I will describe each of these separately.

STARCH.

This substance is very abundant in the barley grain, resembling in outward appearance the other starches found in wheat grain, rice, different palms, and several roots and tubers: on feeling and microscopic examination, however, barley starch differs in its granules from all other starches. Herein lies the microscopic detection made perfect by chemical analysis by which the constituents of the starch is thoroughly ascertained. Barley starch is a white, soft, powdery substance easily separated from the other substance, gluten, by kneading the flour in water, i.e., the flour is first made into a lump by moistening it with water, and then water gradually added as kneading proceeds, until the gluten is entirely separated from the starch as a sticky substance, and the starch remains mixed in the water, gradually subsiding, leaving the surface water clear. This can only be done by allowing the starch-water to be at rest for some time. After the starch has subsided, the water should be drained off, the starch collected, dried artificially, if accuracy is required, at 75°C, or under a strong sun, weighed, again dried, and again weighed, repeating this procedure several times until the weight be found unaltered. The last weight indicates the quantity of starch in the flour.

It should be noted that starch does not contain an atom of nitrogen; the abundance of starch in the barley grain, therefore, forms no criterion of barley-corn as food-grain.

GLUTEN.

Gluten is the other substance found in the barley grain, and is the one on which depends the intrinsic value of barley as food-grain. It is a nitrogenous or blood-producing principle existing in the largest quantity in wheat grain, hence the value of wheat over all other cereal grains as food for man and animals. Starch alone cannot nourish the animal body, for though the large quantity of carbon present in starch is essentially necessary for animal economy in the formation of bile, without which no chylification can take place, yet without gluten no blood and muscles, &c., can be formed. Hence, nature has provided this latter substance very extensively in all food-yielding plants. Another value of gluten is that without it no bread can be made; and according to Mr. Dumas, unless more than 14 per cent of gluten exists in the flour, it is impossible to make bread. The intrinsic value of barley therefore consists in the quantity of gluten it has; the more gluten the more valuable it is: the less, the less. Up to the present time chemists have not fixed the percentage of gluten which should exist in the cereal grain as a commercial standard of intrinsic value of the grain. For barley I think 25 per cent of gluten ought to be considered as maximum; and 50 per cent for wheat. Gluten is obtained in the manner described above: also dried and weighed like starch. Every experimenter and cultivator should try to increase the quantity of gluten in barley and wheat grain. I find Indian barleys very deficient in gluten, not exceeding 10 per cent; also a variety of wheat known by the name of *jannapari*, a variety of the red hard wheat, grown in tracts of Upper India bordering the Jumna, hence the name. This wheat scarcely has more than 14 per cent of gluten, on which account it makes very bad bread, cannot be stretched and shaped properly, and of course is not nutritious. It does not find a ready market in any part of Upper India.

There are chemical elaborate methods of separating starch and gluten, and for ascertaining their weight. They are tedious and impracticable to those who are not analytical chemists. The processes herein described are very simple, not very accurate in the result, but perfectly within reach of every one and everywhere.

MALT PRINCIPLES.

By fermentation, starch and gluten of barley corn are converted into new substances, viz., *asparagin*, *protein compound*, *diastase*, *cholesterin*, *fat*, and *acid*. These are the organic principles found in beer and porter, to which are added several others by the admixture of foreign substances, of which a small percentage of alcohol is always present. Beer and porter are slightly nourishing, stomachic; and intoxicating, if taken in large quantities; harmless drinks or beverages, valuable for females who nurse their

own or others' children. The therapeutic properties of these beverages is *anti-scorbutic*, and are extensively prescribed by the medical profession. These are costly drinks, however.

Ploughing and weeding, same as for wheat, *Indian Agriculturist*, Vol. VII, No. 4, p. 117.

Beds and water channels, same as for wheat, *Indian Agriculturist*, Vol. VII, No. 4, p. 117.

Selection of seed, same as for wheat, *Indian Agriculturist*, Vol. VII, No. 4, p. 117.

Sowing, same as for wheat, *Indian Agriculturist*, Vol. VII, No. 4, pp. 117-118.

Quantity of seed required for sowing one acre, same as for wheat, *Indian Agriculturist*, Vol. VII, No. 4, p. 118.

Habits of growth and remedy, same as for wheat, *Indian Agriculturist*, Vol. VII, No. 4, p. 118.

Irrigation, same as for wheat, *Indian Agriculturist*, Vol. VII, No. 4, p. 118.

HARVESTING.

Like the wheat, barley ear is not provided with glume as an outer protection of the grain, and therefore, if the grain be thoroughly dry on the ear, it is apt to fall down by the slightest touch or even by the action of wind, or by the fall of rain, and get lost. Hence barley requires harvesting at a time when the grain, though thoroughly mature, is not perfectly dry. The best time for harvesting this plant is early in the morning or when the sun is down; should, however, the ear be found in a state capable of being harvested during the day, barley might be harvested even during the day. If the sheaf be broken, wheat cannot get lost, but barley will: the greatest care is therefore necessary both in the time and in the manner barley is harvested. It must be remembered that no rough handling will do for barley. A bunch of barley plant, in the lightest manner, should be drawn with the sickle, firmly grasped with the left hand, and with the right hand cleanly cut out as near the ground as possible without disturbing other plants. This can very easily be accomplished by means of a very sharp sickle. The native sickle cannot do it. It is a blunt, badly-shaped tool made of malleable iron, with a rough handle. The sickle should be of a semi-circular shape, manufactured of pure steel, *case-hardened*, and the cutting part formed and sharpened like a barbers' razor.

The produce of one bunch (selected) of barley produced by me at Sitapore sudder station during the *rubbee* season 1871-72 which having received, in every respect, the kind of cultivation described in this article, contained 100 sheaves, each sheaf, on an average, containing 60 grains. This produce was thoroughly dried, grain separated, and then weighed. The weight was found to be as follows:—

| | Ch. | Tolas. |
|------------------------|-----|---------|
| Seed or grain. ... | 3 | — 1.67 |
| Traves, stem, etc. ... | 2 | — 2.502 |

Based on these figures the produce of one acre will be found from the calculations given below:—

| | Ch. | T. | Mds. | S. | Ch. | T. | Rs. |
|--------------------|-----|--------------------------|------|----------|-----|----|--------------------|
| Grain | = | (288 × 1,320) × (3.167) | = | 1,930.15 | 13 | 2 | 2=162,953.2,99,429 |
| Leaves, Stem, etc. | = | (288 × 1,320) × (2.2502) | = | 1,485.9 | 8 | 32 | =122,213.8,50,800 |
| Total. | .. | 3,465.25 | 5 | 2 | 52 | = | 285,172.1,36,229 |

These should be accepted as reliable maximum data as guide for calculation of manure for one acre of barley on the formula given by Baron Liebig (*vide* heading, *Application of Manure*, of the wheat article. *Indian Agriculturist*, Vol. VII, No. 4, p. 117).

O. L. BRYCE.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

THE Annual General Meeting was held on Thursday, the 1st March 1883.

W. H. Cogswell, Esq., President, in the Chair.

The Proceedings of the last (January) meeting was read and confirmed.

The following gentlemen were elected Members:—

Messrs. F. D. Bellow, S. R. Elson, J. Leadbeater, and the Maharaja of Mohurbhunge.

The names of the following gentlemen were submitted as desirous of joining the Society:—

D. M. Morrison, Esq., Merchant, Calcutta,—proposed by Mr. W. H. Cogswell, seconded by Mr. S. H. Robinson.

Munshi Mado Lal, Zemindar, Munshi of Mirzapore,—proposed by the Raja of Kuntli, seconded by the Secretary.

Major R. C. Corbys, Deputy Commissioner, Shahpore District, Punjab,—proposed by the Secretary, seconded by Mr. J. E. MacLachlan.

Major F. R. Lewis, R.A., Calcutta,—proposed by the President, seconded by the Secretary.

R. R. Waller, Esq., Merchant, Calcutta,—proposed by Mr. S. Cogswell, seconded by Mr. R. Blechynden.

Miss DeMomet, Dooteriah Tea Garden, Darjeeling,—proposed by Mr. John Stalkart, seconded by Raja S. A. Ghosal.

D. J. Zemin, Esq., Calcutta,—proposed by Dr. G. R. Ferris, seconded by the Secretary.

H. J. Joakim, Esq., Merchant, Calcutta,—proposed by Dr. Ferris, seconded by the Secretary.

Rejoined—Dr. G. R. Ferris, Calcutta; Mr. R. J. Carberry, Calcutta; Mr. A. G. Watson, Mr. T. M. Francis, and the Proprietors of the Jugdispore Estate, Behesa.

ANNUAL REPORT.

The Report for 1882 from the Council was read. The Report first enters into details connected with the internal economy of the Society (showing that the number of Native Members is less than one-sixth of the entire list,) and its financial operations, and closes with notice of flower show, garden, &c. The following are extracts on these latter topics:—

"The usual Annual Flower Show was held on the 3rd February, and was equally as successful as that of the previous year, indeed more so in one respect, as the quality of the plants submitted, especially of handsome foliaged ones, was superior to any previous exhibition. The number of visitors (1,500) was beyond the average. The space allotted to each class of plants being extended, admitted of a better arrangement than previously: more time was also allowed for the introduction of specimens. The sum of Rs. 414 was awarded from the general fund besides Rs. 67 from the sum of Rs. 100 placed at the disposal of the Judges by the President.

"Garden.—The stock of fruit grafts, especially of certain kinds most in demand, has been much increased during the past year, which will admit of a much larger distribution than formerly; it is anticipated that the supply will prove fully equal to the demand. This remark is also applicable to Roses, a class of plants for which the demand greatly exceeds that of any other kinds. Some of the newest varieties have been recently introduced which will be in course of distribution during 1883-84.

"Much time and labor have recently been devoted towards a general clearing up of the garden and the removal of several large trees and shrubs, of which there were many specimens occupying a large space of ground which has been better utilized by Rose and other plants much in demand. The majority of these trees were introduced ten years ago to fill up vacant spaces on the formation of the garden.

"The distribution of plants is not equal to last year which indeed may be considered an exceptional year; but it has not fallen short of previous years. Rather more than ten thousand ornamental plants have been issued to members and the public, besides certain economic plants and cuttings; of fruit grafts two thousand five hundred have been sent out. A good many plants have also been granted in exchange and to hospitals and asylums.

"Several subjects have engaged attention, especially those relative to cotton, fibres, and the introduction of superior kinds of potatoes. These matters and many others having been introduced into the monthly proceedings need not be reproduced here, except to notify the fact that in July last the President prepared a full and carefully worded circular letter which was sent to as many as eighty native noblemen, chiefs, and landed proprietors, throughout the country, together with a copy of the last published number of the Journal. The Council have to notify, with much regret, that as yet three only have responded to the suggestion that their names should be enrolled on the list of members. The Council regret to have to reiterate the fact that, while education is rapidly spreading throughout India, the large body of intelligent Hindoos and Mahomedans have not, with very few exceptions, shown that interest in the proceedings of the Society which might naturally be expected from a class who would derive the most benefit. The Council would also be glad if the European members would endeavour to induce their friends to join, so as to fill up the gap annually caused by deaths, resignations, and departures from the country. It has been more than once observed in previous reports that if each member would undertake to add one friend annually to the list, that list would soon be doubled. The Council would, in conclusion, bring this fact again to the notice of members in town and country and urge their hearty co-operation."

At the conclusion of the reading of the Report, the President addressed the meeting as follows:—

Gentlemen,—I feel that the Annual Report for last year, just read, embraces so much and deals so fully with the affairs of the Society, that very little is left for me in the way of comment thereon, but there are a few points on which I wish to touch as briefly as possible.

The Report alludes to the efforts we have made to reach the large number of native noblemen and wealthy influential landed proprietors to join our Society.

It is shown that there were eighty of them addressed, and that out of that large number, three only have responded favourably to our representations.

Surprise only at such a result does not convey my feeling, which is also one of great regret that such indifference characterizes those who should be foremost in fostering a

Society, whose aim and object are the furtherance of landholders' interests, in the improvement of their estates, by a higher and better cultivation of their land, by the use of well selected seeds, and as a natural result, a better and larger yield of crops, and a richer harvest to themselves and to their tenants.

It is doubly disappointing when we think that among such gentlemen there is no lack of leisure, means, and ability, and doubtless in many cases, the taste and application needful to devote to such objects, with successful results; and although I am at a loss to understand such apathy, I still look to that wealthy community with a feeling of confidence that amongst their fixed resident ranks, many may be yet influenced to join us and take an active part in the great and good work initiated and prosecuted with zeal by a few, whose good example should be followed, for they have comparatively but a passing interest in this country, whilst those to whom I allude are in their native land, and with every inducement to come forward and take an active part.

This is the more necessary, for socially, a great change has taken place. The European has become more than ever a bird of passage than formerly. With some exceptions, men are less public spirited and have less time at their disposal. The battle of life is greater, competition is keener, and they have less time to give for the benefit of public institutions; but independently of these facts, there is certainly much less public spirit generally, and not that inclination to devote a portion of what is taken from the country for the benefit of the country. This, I think, holds good with few exceptions, among the higher classes of the official community, who draw so largely from the State. The more rapid communication with Europe has no doubt greatly contributed to this state of things. In former years a young man entering the service of Government commenced life under the impression that he would probably have to work for a certain length of time in the country undisturbed, and that he should give a portion of such time, independently of official work, towards the benefit of those among whom his lot was cast. This feeling was shared by military men in civil and political employ, as well as by civilians generally; now, the object appears to be to endeavour to accumulate wealth and to retire on as early a date as possible, and all our public institutions suffer more or less from this state of things; hence the greater necessity for the native wealthy landed proprietors and others to come forward and take their place and stand in our ranks, and become interested in such work as would redound to their own credit, and whilst forwarding their own interests, they would benefit their country at large.

The Society's records are flooded with valuable information, and bear testimony to the great benefits this country has derived from its labours and influence during the past half-century: records of good work done which cannot be forgotten, and requiring only the support and encouragement of those to whom I have alluded as an additional reform, or adaptation, to meet the new times and enable the Society to increase in the number of its adherents, in its wealth, and in its great influence, and for the accomplishment of which I appeal to all those who have its interests at heart to continue unflagging their efforts to further its prosperity.

With these observations I have pleasure in proposing the adoption of the report.

The report was unanimously adopted, and the best thanks of the meeting were voted to the President for his interesting and appropriate remarks. The election of officers and council was next entered on with the following results:—

President.—Mr. W. H. Cogswell.

Vice-President.—Raja Suttayanund Ghosal Bahadoor, Mr. W. Stalkart, Mr. H. A. Firth, and Baboo Protapa Chundra Ghosa.

Secretary.—Mr. A. H. Blochynden.

Council.—Mr. J. E. MacLachlan, Mr. R. Blochynden, Dr. G. King, Dr. S. Lynch, Baboo Peary Chand Mittra, Mr. S. Cresswell, Maharaja of Cooch Behar, Mr. G. L. Kemp, Mr. S. H. Robinson, Baboo Joykissen Mookerjee, Mr. John Martin, and Mr. D. Crutskshank.

HORTICULTURAL EXHIBITION.

The reports of the judges on the annual show of vegetables, fruits, and flowers were submitted as follows:—(Judges: Dr. S. Lynch, Mr. W. Stalkart, and Mr. John Lynam).

Horticultural.—The exhibits for which prizes were offered on this occasion was on a comparatively limited scale on account of the limited space at disposal, not more than 14 kinds of vegetables and twelve of fruits. The quantity in each basket was also limited. Notwithstanding the announcement being widely notified to the intending competitors, many baskets contained more than the prescribed number, and several other kinds not in the list (notably, cauliflowers, turnips, knolekole and cabbages) were introduced into the tent. Though some of them were well grown specimens, the judges were not in a position to award prizes to them. However, in some instances, they did not think it desirable to adhere strictly to the rules laid down as to the number of each kind, this being the first attempt, under the new system, of restriction in quantity.

Among the vegetables, there was a marked improvement in celery. Carrots and potatoes were also well represented, and artichokes (out of season). Tomatoes and beet were excellent. Peas and French beans were fairly good.

In the list of fruits, basil showed well; there were some good specimens of pine-apples, pappas, and guavas—though out of season. A special prize was awarded for a small China orange tree laden with fruit.

Altogether the show was satisfactory, fifty market gardeners competed and fully 350 baskets were shown. Prizes were awarded to 24, amounting to Rs. 160, of which Rs. 99 were for vegetables and Rs. 61 for fruits.

Floricultural.—(Judges: Dr. G. King, Messrs. G. L. Kemp, H. A. Firth, and Raja Suttayanund Ghosal Bahadoor.)

The collection of plants was rather less than last year, but the quality of those exhibited was equally as good, and in some instances better. The competition was much the same—18 gardens of whom 14 gained prizes. There was a good collection of handsome foliage plants, notably crotons, dieffenbachia dracenas, marantas, anthurium, aralias, begonias, including several new kinds. The collection of cut flowers, especially roses, was excellent—far superior to last year. One collection of roses from the garden of Mr. G. A. Forbes at Barrackpore deserves special mention, but no prize could be awarded to it as it was sent too late. Among the annuals were good examples of asters, pansies, violets, and verbenas.

The Royal Botanic Garden contributed a very interesting and much larger collection than last year, occupying seven stands, of three tiers each and 9½ feet in length. Of many fine plants the following may be mentioned as among the newer—namely, piper magnificum, anthurium, warocqueanum, dieffenbachia marmorata, D. parlatores, D. maculosa, D. Braziliensis, aralia veitchii, A. elegantissima, selaginella magnifica, S. paradoxa, dracena benthami, philodendron carderi, heliconia auroo-striata, phyllagathis rotundifolia, lindsaya pectinata, sphacrostemma marmorata, allomorphia griffithii, dichorisandra musaica, trenesia moluccana, ptychosperma singaporensis, schismatoglottis longispata, and centrasclenia aurea.

There were three competitors for the "Grant Silver medal" for the best collection of plants or flowers of any number of kinds. The medal was awarded to Baboo S. P. Chatterjee.

Extra prizes to the value of Rs. 51 were awarded from the sum (Rs. 100) placed again by the President at disposal of the judges for rare or well grown plants not included in the schedule, and Rs. 411 were awarded for the latter. A detailed list is hereto annexed.

The attendance of visitors was less than last year, attributable probably to its not being a public holiday. Their Excellencies the Viceroy and the Marchioness of Ripon, and his Honor the Lieutenant-Governor and Mrs. Rivers Thompson honoured the show with their presence.

The thanks of the Society are due to Colonel McNair and the Officers of the 4th Regiment N. L., for the services of their band on the occasion.

A report from the Garden Committee was introduced and adopted in respect to provision of vegetable, flower, and agricultural seeds for next season from Europe, America, and Australia.

MAIZE OR INDIAN-CORN.

The Secretary submitted the following few notes which he had prepared in connection with some cobs or ears of Indian-corn, which had been recently sent down from Tirhoot:—

Colonel Money, the Manager of the Durlhunga Raj, has sent us two cobs of maize raised in the Raj Garden. It appears from their size and general appearance that they have been raised from imported seed; probably from the kind we import from Philadelphia as "Yellow Canada," to which they are fully equal in every respect. [I placed these on the table at our show on the 7th February, and so highly were they appreciated that they were stolen by one of our many visitors, the sheaths only being left behind.] I have requested Colonel Money to inform us of the stock from whence derived, the soil in which grown, and the manure employed. If maize of this character can be raised in India in any quantity, we should be able to compete successfully with the United States in the English market.

It would appear that the quantity of Indian-corn taken by England from abroad, chiefly from America, in 1881, was upwards of 33 millions cwts., or considerably more than half the total imports of wheat. In a recent article in the *Englishman* it is stated that "the shipping of Indian-corn in merchantable quantities began in the latter end of December last, but was discontinued early this month (February), owing to the want of supplies of a sufficiently good quality. During this short period between twelve and thirteen thousand bags were shipped; and when the new season begins next month, a very large business is expected. This business can, however, be but insignificant compared with what it might be if the Government of the country were properly alive to its true interest in establishing cheap communications between the coast and such rich, but isolated, tracts, as the greater part of the Central Provinces, which are alone capable of supplying all the Indian-corn England requires, without any serious rise of prices. Here is a potential addition to our export trade of probably not less than five millions sterling per annum, which only needs a little more enterprise for its realisation."

Referring to the above remark as to the capabilities of the Central Provinces, in which may be included Central India, I may observe that many years ago (1838 or 1839) Colonel Dixon, then Superintendent of Ajmere and Mhairwarra, called the attention of the Society to the very inferior size of the Indian-corn raised in those districts. At Colonel Dixon's request the Society forwarded him large quantities of imported American seed for several consecutive years which he reported had greatly improved the character of their stock. Whether it has since deteriorated I am unable to say, but am making enquiries thereon.

The outer sheaths on these cobs, of which it will be seen there are many enveloping each cob, and which are now either thrown away or used as fuel, would most probably prove a valuable addition to our stock of paper-making materials.

Whilst penning these few notes, I have received a useful contribution from Captain Pogson, on "Maize as a paper-producer," which I introduce here in connection with the above remarks, so as to render our information more complete and interesting.

"Maize is cultivated all over India, but partly from want of knowledge and partly from want of organization, the portion of the cob which yields a superior material for manufacture into paper is almost as a rule burned. In Germany, Austria, and Hungary, a very superior kind of paper is made from the sheaths or envelopes of the maize cobs. Maize paper has none of the brittleness peculiar to ordinary straw paper. Maize paper appears to be the most unexceptionable of the papers not made from rags. Not only is it remarkably tough, but it is devoid of all the silicious matter which proves so embarrassing in ordinary straw paper, causing great brittleness when folding and rapidly destroying the face of printers' type. The extreme toughness of the paper makes it particularly eligible for Bank note paper and for the purpose of envelopes. The colour is somewhat yellowish, but it is easily bleached."

This really valuable information (whence derived is not stated) is all but lost in 4½ columns of matter connected with maize cultivation, and to be found in the *Indian Agriculturist* for September 1881, at page 250.

There is a first class paper mill at Lucknow, and the Maharaja Scindia started a paper mill now in the market. Now if any suitable organization existed, all the maize cob sheaths produced by the zemindars of Oudh, might be made to find their way to Lucknow, for conversion into superior paper, and in like manner, if Scindia's paper mill was set up in the Allyghur district, on or near the Ganges Canal, all the maize grown within 50 miles on each side of the Canal would yield up their cob sheaths to the paper-maker, and we should see Upper India producing first class paper from what is now looked upon and treated as a valueless waste substance.

The Agricultural Department could very easily cause it to be made known that if the zemindars preserved the Indian-corn cob sheaths, purchasers would be found for the article, and then one paper mill would not suffice to work up the material made available from Hurdwar to Allyghur, leaving all below Allyghur to be utilized at Cawnpore, where another paper mill should be started.

There is ample money in the country to carry out the project, and if ventilated through the proceedings of the Society, would carry great weight. I venture to predict that the thing would be done.

Since the above was written, I have had a communication from Mr. Maries, of the Raj Garden, informing me that the maize he has sent down was grown in light garden loam, and cow and horse-dung used in trenched ground about 15 inches. Seed was sown in September, fit for use in December, and was obtained from Veitch and Sons, London, as Canada early Maize. The cobs sent were not selected ones, the whole crops being alike.

And Mr. Parsons, the Superintendent of the Ajmere Garden, has kindly afforded me the following particulars in response to my application:—"The maize grown in the immediate neighbourhood is a very small yellow kind, both cobs and the grain itself being inferior in appearance. In favourable seasons, however, good crops are obtained from it. This kind has, I am told, been cultivated from time immemorial. I am further informed that Colonel Dixon sent the maize he imported into Merwarra, where there is now a white kind grown said to be not indigenous to the district. It is not, however, brought into this part for sale, and I have not seen it myself. Should this be correct, it seems strange that it was not established in the Ajmere district also. I have been over a considerable part of it, but have never met with any kind but the one I have referred to. Mr. Saunders, the Commissioner of Ajmere, Merwarra, is now on tour in the last-named district, and I have sent your letter to him. If he can procure further information on the subject, I will write again on hearing from him."

RESULT OF TRIAL OF KIDNEY POTATOES IN THE NURSERY GARDEN WITH POTATOES RAISED IN AMERICA FROM ENGLISH STOCK.

A report from the Garden Superintendent (dated 20th February) was read, in respect to the culture of certain potatoes presented in November last by Mr. W. Stalkart:—

"The receipt of, and planting out, of these potatoes has already been reported on. The supply, presented in a small box, was too far advanced towards germination to admit of weighing or the least rough handling; but for practical purposes it may be correctly considered the presentation weighed four seers. The space occupied by the potatoes in the box having been refilled with fresh gathered potatoes and weighed, the result being four seers."

I am sending up a small quantity of earth to show the soil the same was grown in, which is not too stiff, reasonably light and friable. The potatoes were planted out entire, uncut, as in that state I considered them less susceptible to mildew, rot, and attacks of ants, a handful of old well rotted cowdung being placed round the tubers. In the course of three weeks the vines having well developed, were earthed up, an additional handful of similar manure being supplied. Watering was continued from date of planting pretty freely, till the beginning of this month (February), when the supply was gradually lessened, my main object being to avoid the possibility of the vines flowering. A couple of days since I observed red ants, and unearthing found the mischief to the potatoes had begun. All the potatoes were unearthed yesterday, and the following is the result:—

| | | | |
|--|-----|--------|-----------------------|
| Sent to Secretary's office on 19th February 1883 | ... | 1 seer | good potatoes. |
| Sent to Secretary's office on 20th February 1883 | ... | 18½ " | " " " |
| Sent to Secretary's office on 20th February 1883 | ... | 1½ " | small " |
| Sent to Secretary's office on 20th February 1883 | ... | 4½ " | attacked by red ants; |

The vines had not withered when the potatoes were gathered, but I could not defer the same owing to the red ants; I should much wish to plant out a similar quantity early in October next, which I think would be a most favourable time for experiment.

Many of the tubers are as large as those put down. I boiled a couple and found them of good colour and flavour."

Mr. Stalkart showed some fine specimens of potatoes raised in his garden from the above and other kinds. Mr. West exhibited some well grown seedling tuberos rooted *begonias* in full flower.

Mr. Maries sent down from the Darbhunga Raj Garden some fine cut flowers of pansies, plucks, and stock.

AMERICAN SUMACH.

The secretary called the attention of members to the subject of American sumach or divi-divi (*Cassipouia coriaria*), in connection with a small quantity of seed recently gathered from a few trees in the Society's Garden, and to the enquiries now being made in respect to this valuable plant. He submitted a paper he had drawn up showing what the Society had done in the matter nearly forty years ago, and brought to notice certain skins tanned by the pods, and specimen of the pod itself, all which had been in the museum during this long period. He had prepared this paper to show that the Society had been the first in the field not only in respect to this, but many other useful products, which are now and again introduced as novelties to public notice.

The paper was transferred for publication in the number of the Journal now in the press.

MUDDAR PLANT.

The secretary submitted another paper on the muddar plant (*Calotropis hamiltonii*) and its useful properties, and laid on the table specimens from the museum of cloth made therefrom some 30 years ago. In the proceedings of the Society there occur several notices regarding this jungly plant which may not be generally known or are now lost sight of. Considering it might be worth while to reintroduce the facts, notified so long since for the information of readers of the present day, he had drawn up a few notes thereon. (Transferred for Journal.)

OFFICIAL PAPER.

ESTABLISHMENT OF FUEL AND FODDER RESERVES.

Extract from the Proceedings of the Government of India, in the Revenue and Agricultural Department,—Dated Calcutta, the 1st March 1883.

THE attention of the Government of India has lately been called by various reports and statistical returns from the Upper Provinces to the growing decrease in the area of grazing lands and wooded tracts in many parts of Upper India. These remarks have special reference to the Provinces of the Punjab, the North-West, and the Central Provinces, inclusive of the Berars. The grazing land in these provinces has not only diminished in area, but has also deteriorated in quality and changed character, the latter result being partly due, as will be presently explained, to the excessive grazing which the reduction in area has made necessary. The Government of India is aware that efforts have been made both by the Local Governments and district officers, especially in the Punjab, to meet the difficulty; but it appears necessary that more systematic measures and arrangements should be undertaken than have yet been instituted in any province. The Famine Commissioners have not omitted to give prominent notice to the subject in Part II of their Report.

2. The decrease of the area of culturable waste is a natural consequence of the increasing numbers of the agricultural population, by whom a continually extended area of arable land is required for the plough. The argument indeed has been brought forward that the grazing lands and jungles, of which the cattle of the country have been deprived by the encroachments of agriculture, can be profitably and efficiently replaced by fodder crops, and that such has in fact been the case in many countries in which agriculture is more fully developed. But it is doubtful how far it is wise to allow this argument to be applied at present to the Upper Provinces of India. The one fact that these regions are subject to droughts of a character unknown in the Western hemisphere, places them on an entirely different footing from those civilised countries with the agricultural system of which we are most familiar. In a season when a failure of the monsoon causes the destruction of crops which supply food for men, those crops also upon which cattle depend are equally liable to perish. It is only in tracts which are thoroughly irrigated that any safe reliance can be placed upon a supply of artificially-raised fodder, or that a system of stall feeding can be expected to preserve the lives of the cattle,

Tracts so protected form at the present time a small proportion of the agricultural area of Northern India.

3. The history of the famines and droughts which have occurred during the present century, and especially in late years, is replete with painful accounts of the wholesale destruction of cattle by starvation and the failure of the fodder supply. It may be doubtful whether the loss which the agricultural population has thus sustained has always been fully appreciated. At a time when they have been deprived by a failure of the rains of a great portion of the produce of one or more seasons, they have also had taken from them, in the destruction of their plough-labour, the means of recouping their loss in succeeding years. The late famine of 1877 has furnished many examples of this kind. Accounts have reached the Government of India of the serious deterioration of the agricultural prosperity of many tracts which, there is every reason to believe, would now be in a flourishing condition if the cattle could have been saved. On the other hand, instances have been brought forward in which the existence of a sufficient area of grazing land has, in districts most affected by the drought, both preserved the cattle and secured the agricultural population from prospective loss.

4. It is desirable at this point to explain that the term "grazing land" as herein used, is not to be restricted to land which provides nothing but the ordinary pasture of a grass plain. Such land is often affected just as seriously by a drought as the unirrigated area of cultivated land. Grazing land is here intended to include those wooded tracts and jungles which provide bushes, trees, and herbs from which cattle can obtain a plentiful supply of fodder, even at times when the grass on open ground is dried up and destroyed. There are many trees and many bushes which, drawing upon a supply of moisture below the surface of the earth, can maintain their life and vigour when the shallow-rooted crops and grasses are parched and withered. And this is not all. It has also been ascertained that the grass itself which, on an exposed surface, would succumb to the drought, is, in the cooler atmosphere occasioned by the shade and protection of trees and shrubs, saved from destruction.

As, moreover, there is, apart from the question of fodder, a distinct agricultural advantage in maintaining throughout the plains of Upper India a supply of wood for fuel and domestic purposes, the term used in the following paragraphs of this Resolution to designate grazing lands will be that of Fuel and Fodder Reserves.

5. A further effect of the absence of proper food after a period of drought is that the cattle, which have been starved for weeks, feed too greedily on the young shoots of the millets that are sown with the first showers of rain, or on the coarse grass that springs up on the return of the monsoon. The excess of food to which they have been unaccustomed induces a rapidly fatal disease which has carried off thousands of animals in many parts of India.

6. Instances are quoted in which cattle perished in large numbers from want of fodder in the droughts of 1877 and 1880; while, on the other hand, cases are noted in which they were saved by being fed on bushes and leaves of trees. In Rohtak, for example, no less than 250,000 heads are said to have died, or about one-half of the whole cattle of the district. This was in 1877. In 1880, 15,000 cattle are reported to have perished in this district of Jhansi, while many others were only preserved by the bushes in the ravines or by fodder obtained from trees. In the same year large numbers of cattle were in the Allahabad Division kept alive by being taken to the forest tracts of Banda, while throughout the division all the available trees were stripped of their leaves. "There is no need," writes the Commissioner in quoting from his district reports, "to multiply these extracts, all of which tell precisely the same story."

7. The examples to which reference has now been made are sufficient proof of the necessity of taking some action for the protection of the cattle of the country against drought. The facts brought forward seem to prove that at present the agricultural population will not or cannot themselves take sufficient precautions to provide against exceptional occurrences. They trust to accident or to assistance from the Government. But in this matter little or no help can be afforded, unless systematic arrangements are made in advance, and continuously maintained, under which a supply of fodder in a year of drought may be secured. It is necessary, therefore, to consider in what form, system and continuity can be most advantageously established; and it is on this point that the Government of India is mainly desirous of obtaining the advice and co-operation of Local Governments.

The general outlines of the scheme which commends itself to the Government of India as most likely to secure the desired results, and which from enquiries already made appears likely to meet with

the most general acceptance, will be briefly described in the following paragraphs.

8. The general control and administration of the measures with which this Resolution is concerned should, in the opinion of the Government of India, be primarily in the hands of the local officers, viz., the Commissioner, the District Officer, and his subordinates in charge of sub-divisions. The official channel through which the Local Government would communicate with the divisional and district officers would be the Agricultural Department, which would be responsible for providing the Government with advice and information, and for maintaining continuous action. The actual management of the lands set apart for the supply of fodder and fuel would be placed in the hands of Forest officials, who alone can be expected to establish and maintain without interruption a scientific system of treatment.

9. In order to satisfy the above conditions, it would be necessary, in each district or division in which operations are likely to be sufficiently extensive to require scientific management, that an officer of the Forest Department should, when financial circumstances admit of this being done, be placed under the orders of the district or divisional officer. He would work entirely under the orders of the Civil officer, who would, however, refer questions of a professional or technical character for the advice of the chief Forest Officer of the province or circle. In many districts the necessary staff exists already, but in other new posts will have to be created.

It must not, however, be expected that arrangements can be made, financially or otherwise, under which every district or division can, in every part of the Upper Provinces in which the measure would be useful, be supplied with a separate Forest Office for the work contemplated. It would, indeed, be extremely unwise to enter upon any expensive organisation until much more experience and information has been acquired. It is only, therefore, for those regions in which grazing lands are disappearing at a rapid rate, or in which history has shown that drought causes extensive destruction of cattle, that any application for the services of special officials could at present be entertained. It will probably be considered sufficient if at first a Forest official is attached as assistant to the Commissioner in one or two of the divisions in each province in which protection is most required.

10. In the meanwhile the serious duty will devolve upon the district officers of ascertaining how far the cattle need protection, and the extent of land, whether the property of Government or purchasable from land-owners at a reasonable price, which can be made available for fuel and fodder reserves. For this purpose an analysis of every district should be made by the local officials which will show its need for protection against drought, and the extent to which land is available for fuel and fodder reserves. They may also be directed to enquire how land can be most advantageously secured for the required purposes in districts where a sufficient quantity of Government land is not available, how far the landholders themselves or local boards will be able to co-operate with the Government in the matter, and at what cost suitable areas can be procured.

11. The Agricultural Department will probably at present be most usefully employed in ascertaining, by actual experiment, and in consultation with the Forest Department, what are the best means of bringing waste lands into a condition in which they can most economically provide a supply of fodder in a year of drought, and in what way they can in ordinary years be most profitably employed. The Department would also superintend, in correspondence with Commissioners, the analysis required by the preceding paragraph, and would review for the local Governments the reports received from each division. The same department may also ascertain whether any system of stacking hay or storing fodder can be established, or whether it may not be useful to close grazing reserves for a portion of the year, especially when other fodder, such as the stubble of newly-reaped crops, is available. For if grass reserves are only thrown open when no other food is available, the grass will have the requisite opportunity to make head, and will thus provide a much more ample supply of fodder than if exposed continually to desultory grazing. Enquiries of this kind will fall within the scope of the Agricultural Department.

12. This Resolution is not the place in which the treatment of land required for conversion into fuel and fodder reserves can be considered in any detail. But the opportunity may be taken to give expression to the opinion of the Government of India that little real good can be effected unless the reserves are, at any rate for some years, brought under the control of Government, and systematically protected against the invasion of goats, cattle, and fire. It appears to be a matter susceptible of proof that a protected

area will, besides giving security in a year of drought, afford over a certain number of years a considerably larger amount of fodder than an unprotected area of equal extent. It seems probable that the difference is sufficiently great to admit of a hope that fuel and fodder reserves can, in a large number of instances, be made financially successful. The importance of this view deserves some further examination of the question. The following illustrations may therefore be adduced in support of the view which has now been brought forward. In his Administration Report for 1879-80, the Inspector-General of Forests shows in the following words the results of protecting grazing land :

"In all except the most arid tracts, or where denudation has been complete and of long standing, mere protection, aided by sowing and planting in suitable places, has the effect of gradually clothing the ground with trees and shrubs. What happens is this,—the old stumps and roots in the ground produce shoots ; seeds which have been lying in the soil, and seeds brought by the wind, germinate ; the shoots and seedlings, which without protection would have been destroyed by the fire or eaten by the cattle, grow up ; and wherever there are sufficient remains of the old forest growth in the ground, the result is most remarkable. The difficulty consists in this—that new reserves must be formed, and that, during the first few years, this unavoidably entails some restrictions in the matter of grazing. At first the protection of the areas selected must be absolute, and the people in the vicinity can neither be permitted to burn the grass, nor graze their cattle in these areas. But the grass which grows up abundantly can be cut, and thus furnishes abundant cattle fodder until the forest is sufficiently advanced to admit of grazing."

13. In Ajmere the results of enclosing areas, hitherto barren, with the object of securing fodder for cattle in times of drought, are already remarkable.

"After five years' conservation there is much in these forest reserves to encourage us ; the appearance of the hills and countryside in these tracts is quite altered. The people even have begun to recognise the advantage to be obtained by the experiment we have introduced. We have been blessed with another year of plentiful rainfall ; the undergrowth has become in places in Mairwara nearly impenetrable, and in the ravines and valleys I have been surprised to see the number of fine young trees springing up. Our great enemy now is fire"—*Ajmere Forest Report, 1879-80.*

Grazing is strictly prohibited, but the villagers are allowed to cut and carry off the grass on pack animals. The cash receipts are at present small, but the benefits which the people indirectly enjoy from these reserves are very considerable.

14. Again, in the North-West Provinces, various experiments have for three years been conducted by the Agricultural Department, with the view of reclaiming *usar* or *vak* land—i.e., land rendered more or less unculturable by the excess of salts in the soil. It has been found that the simple expedient of enclosure is more efficacious than any other operation. The natural grasses which, so long as the land is accessible to cattle and goats, are nibbled down as fast as the young shoots appear, spread in the enclosed areas at a rapid rate over the worst land. After two years, experimental cuttings gave a result of 20 maunds of good hay per acre—an outturn which on a square mile would suffice to feed 1,000 cattle for three months, exclusive of the bushes and trees which, there is good reason to believe, can be grown when once the grass is well established.

15. The terrible devastation caused on unprotected land by sheep, and the impossibility of re-covering forest and undergrowth once lost so long as the land is exposed to the grazing of sheep, is forcibly brought out in a late report by M. Boppe, Inspector of French Forests, on the Forests of Scotland, from which extracts are quoted in Appendix D. His remarks on the greater value of land for purposes of grazing after enclosure are, in connection with the suggestions made in paragraphs 11 to 13 of this Resolution, especially deserving of notice. The present barren condition of the greater part of the waste lands of Scotland is attributed by M. Boppe almost entirely to one animal—the sheep. There is very strong ground for believing that the goat, which may be said to take the place of the sheep in India, has been the one chief cause of the present barrenness of large tracts of country in Northern India.

Extensive areas now bare are known to have been once covered with a rich growth, if not of forest, still of scrub and grass that would, if not destroyed, have formed a rich pasturage; animals may not have been the original cause of the disappearance of the vegetation, but they have been the constant cause which prevents renewal of growth. No more striking instances, indeed, of the effect of the natural recovery which ensues when goats and cattle are excluded

can be found than in a comparison between those hills in Ajmere which have for four years only been enclosed, and those which have remained open to goats and cattle during the same term. The first are covered with an almost impenetrable thicket chiefly composed of shoots edible by cattle ; the second are practically devoid of all vegetation, and appear to be mere heaps of rock and stone.

16. If the conclusions indicated by the facts and arguments adduced in the preceding paragraphs can be accepted, the objection which has not unfrequently been brought forward to the occupation of grazing lands on the score of the inconvenience suffered by the adjacent population in being deprived of their cattle pasture is greatly diminished. The occupation is only temporary. The inconvenience which is temporarily occasioned to the agricultural population is due to their own action in diminishing the efficiency of their grazing lands by an improper use of them. The Government proposes to do no more than restore, and, if possible, to increase, the efficiency which has been lost. The measure contemplated will, it is believed, result in a future supply of fodder, which will be far larger and far more certain than that of which the owners of the cattle have been deprived. In this view it may be even found desirable to attach for conversion into fuel and fodder reserves land which has been broken up under plough, but which, as fodder reserves, would be more profitable in preserving cattle from starvation, than in growing crops which are subject to failure in a year of drought.

SELECTIONS.

SCIENCE IN AGRICULTURE.

THERE are too many dabblers in science. In regard to the incomplete, uncertain, and intricate laws which relate to agriculture, and which go to make up what may be regarded as the science of this art, this is especially true. This is a great mischief and damage. Not that the mere study of the science of agriculture or its consideration by farmers can be in the least harmful or conducive to anything but good ; but that so many persons who never turned a furrow, or sowed a seed, or watched a plant grow from its first sprout to its maturity, and who never fed an animal, or watched its thrift and growth under the influence of feeding and management, but who have read perhaps one book upon the subject, or have attended a course at an agricultural college, will pretend to expound this most intricate science with all its profound and unfathomed depths. And thus they lead men astray who know no better than to follow their second-hand ideas, wretchedly distorted and perverse as they may be, or disgust those who are better acquainted with the subject, and are able to see the errors and blunders and misconceptions into which these "writers upon agricultural science" ignorantly fall.

There is not so much of this seen in regard to any other art than to this "art of arts." Science is the handmaid of every art. By its light and help the industries of the world are guided and led. But there is no other science in which there is so much confusion, and at the same time so much difference of positive statements and so much disputation as to principles and operations, as in that of agriculture. There are other arts of which an exact scientific knowledge is quite as desirable, such as metallurgy, the reduction of ores, dyeing, tanning, &c., but in these there are not nearly so many or so great differences of opinion as in regard to the growth of plants and the sources from which plants derive their substance. Nor is there any other subject of scientific inquiry in regard to which so many positive beliefs are so rudely and completely upset and displaced as in this. A study of the history of agricultural chemistry and physiology brings to mind the mistakes and errors of the old alchemists, the founders of the science of chemistry, as they groped in the dark, before the dawn of light fell upon them, and which were simply truths half learned, and facts only dimly seen or perhaps not seen at all, but merely recognized in part by their effects. And as the daylight dawned, and these facts were viewed in the full light, and viewed on every side, and their relations were better understood, knowledge became accurate, and demonstration took the place of opinion and belief. What a cloud of misunderstanding was swept away by the discovery by Dalton of the ultimate constitution of matter, and upon which he founded his atomic theory ; no longer a theory but a recognized law, although it is proved only by indirect and secondary evidence, and

Show is held we trust that some convenient method of displaying the samples submitted will be devised, and that on another occasion more space will be allotted to this class of produce. The other fibres made a fair show, but though we visited the Exhibition with every intention of adding to our knowledge of the subject, we were not able to learn much, and the judging did not afford us much guidance; probably the Stewards of the section were not able to tell the judges what there was competing. The judges remark that "the specimen of Manila hemp shown was discolored and weak," but we noticed a small sample not competing, exhibited by the Saidapet Farm, which, although extracted by hand labour and at considerable cost, showed that it is possible to obtain good fibre of this kind, and that the great problem is now to extract it, in great lengths, economically. The magnificent specimens of the plant which yields this valuable fibre, mistaken by many we imagine for common plantain plants, which stood just inside the main entrance, showed that even in the climate of Madras supplies of the fibre can be raised, whilst on the West coast it grows luxuriantly and almost without any trouble. As the judges remarked, the show both of green and dry fodder was very poor, and, considering the work which has been done at Saidapet in this direction, disappointing; here, again, the rule preventing Government institutions from competing for prizes, prevented public attention from being drawn to some excellent exhibits from our Government Experimental Farm.

In the class devoted to special and plantation produce, the arrangements were better, partly because there was not so great a variety, but chiefly because one of the judges (not a steward) visited the exhibition before it was opened, and aided in arranging the articles which the overworked staff were struggling by hook or by crook to get into something like order in one-fifth of the time necessary to do it satisfactorily. Here we noted that no proper arrangements were made for treating such articles as cannot be judged by inspection, such as bark, for instance, and we did not at all envy the judges in their labors. Regarded as a whole, the show in this class can only be regarded as fair, and we must remark that we regard oilseeds and fibres as being just as much "special produce" as sugarcane, or indigo, and other dyes. There were some very fine specimens of sugarcane exhibited, but the finest specimen came from beyond India, and we are glad to hear that it received the first prize; its exclusion from a prize would have been most ill-advised, for we want to know where the finest produce can be grown, just as much as to encourage the growth of fine produce in India. When it is known where good seed can be obtained, it will be easy to obtain it, and distribute it to our ryots, in lieu of their own inferior sorts, and whether a bundle of sugarcane comes from the Straits Settlements, or from Bellary, it is equally deserving of a prize. Encouragement to the introduction of good staples is just as important as encouragement of their growth, and until it is known whence good staples can be procured, introduction cannot proceed. The exhibits of forest produce were disappointing although several fair collections of woods were shown; still, here again nothing could be learnt regarding their respective costs. Tassa silk cocoons came fairly well to the front, and there were several exhibits of honey; whilst Dr. Shortt's bee-hive attracted a good deal of attention.

The division of the exhibition devoted to manufactures and miscellaneous articles drew crowds of visitors, but we question the advisability of mixing up laces and harrows, silk cloths and chillies, in the same exhibition; and in this particular case, it is very evident that the Committee were unable to cope with the difficulty of displaying these exhibits, whilst the space available was absurdly inadequate. Some of the articles included in this section no doubt properly appear in an Agricultural exhibition, e.g., cumbies, reeled silk, canvas and gunny, bricks and drain pipes, and ropes, but others were much out of place; and if it is desired to hold exhibitions of the local manufactures, the work should be done separately, although perhaps it might be usefully connected with an Agricultural Exhibition. In the list of prizes for miscellaneous articles, there was nothing particularly out of place, but we fear that there was considerable repetition, and that exhibits of the same substances might be made both in this and in the class devoted to special produce. The wool shown was all coarse and inferior, but not so bad, but that a few crosses of good wool-bearing breeds would render it a valuable article for export. In the jaggery also, we notice some excellent exhibits from Salem, but here also no indication was given as to the price. We also noticed a small example of very fair-looking jaggery, made, we learn, at Saidapet, on the usual native system from the juice of the Amber sugar-cane, a variety of the Chinese, *Sorghum Saccharatum*, which should encourage any one interested in the matter to attempt the growth of this crop in the other parts of the Presidency, for, if its growth can be made successful, and good jaggery made from the juice, there is little doubt that the sugar trade of the country will be revolutionised.

And now we must cease from our pleasant duty of recording our observation on this, considering all the difficulties to be contended with, most successful Exhibition. Whilst we have been unable to do otherwise than criticise the defectiveness of the arrangements in several ways, we are quite aware that, in a practically new undertaking, under untried circumstances, and with no experience to guide them, the Committee have achieved a great deal; and we hope that when, in a few years' time, another exhibition is held, the then Committee may be as successful in getting together as good a show of the manifold productions of the country, and that the minor faults we have noticed may be conspicuous by their absence. To facilitate this, all the experience gained now by the Committee, Stewards, and Secretary, should be recorded for the guidance of those who may come after them. We hope that the present Secretary, Mr. W. R. Robertson, M.R.A.C., may have the pleasure of organising many more exhibitions for us before he vanishes from this country, the great agricultural wealth of which he has so long been striving to develop.—*Madras Mail*.

LIGNIFICATION AND ITS TECHNICAL ASPECTS.

ON the 25th of January a paper was read at the Society of Art by Mr. C. E. Cross, dealing with the subject of the treatment of wool and woody fibres for the purpose of manufacture. The whole question was handled in an able and interesting manner, but the points of practical importance to paper-makers were those relating to the processes for treating wood and other resistant vegetable substances for the preparation of paper pulp, and the modifications of these, which we can show to follow from what is known of the composition of these fibrous structures. Up to within a comparatively recent period, these processes have consisted uniformly in a drastic treatment with alkaline solutions; the process of boiling under pressure with caustic soda, originally applied by Routledge to esparto, has been generally extended and adopted, and is, indeed, the standard method of treating lignified substances for paper-making; efforts to substitute this process by one based upon the principle of reduction or anti-oxidation have been made by one or two technologists, who, at the same time, do not appear to have approached the subject from the same point of view. The subject appears to have been developed most consistently by Fry and Ekman, and as their labours have had strict reference to the principles under discussion, their treatment will occupy the prior place.

Fry commenced the investigation of this subject about 17 years ago. He was familiar with Houghton's process, the object of which was to throw the work of disintegrating the wood upon the agencies other than the alkali, which latter it was found could be proportionately reduced in quantity. Fry was led to investigate the resolving action of the water alone, under the guidance, not unworthy of mention, of a passage in Faraday's "Manipulation," which directs the chemist, in analysing a mixture, to adhere to the method of preliminary separation by means of solvents successively applied, of these water being the first. It was found that water, at sufficiently high temperature and pressure (70 lb. of steam), exerted a very considerable disintegrating action, sufficiently indeed to produce a pulp well adapted to the manufacture of brown paper; also that of the soluble products of resolution a large proportion were acid bodies. The following statistics, having reference to the two processes, are worth reproduction, the wood operated upon being in both cases that of the common *Pinus Sylvestris* :—

(1.) *Houghton Process*.—3,378 parts (dry) wood, yielded 1,787 parts dry pulp = 33 per cent.

(2.) *Water Process*.—6,338 parts (dry) wood yielded 4,424 parts dry pulp = 70 per cent.

The process of disintegrating the wood by means of water, at elevated temperatures, was worked to a practical issue, and a mill was put up at Bergvik, in Sweden, for the manufacture of "half-stuff" for brown paper. At the same time, investigations were continuously prosecuted with the view to increase the solvent action of the water, and thus to arrive at a product more nearly approaching cellulose. It became more and more evident that the condition of oxidation was especially inimical to this end, and to antagonise it by the presence of a reducing agent was the purpose which underlay the next series of experiments. These were carried out by Ekman, and his choice of a reducing agent soon fell upon sulphurous acid, a choice which was perhaps in the first instance determined by a natural fitness on the side of economy, but is now seen to have the more important function conditioned by the peculiar relationship of the sulphites to the aldehyde products of resolution of lignose. The results which followed from this modification, the removal of a further 20 per cent. of the non-cellulose constituents of the wood, and the production of a residue which is but little removed from pure cellulose, are now matters of common knowledge. The special commercial advantages which this process offers, viz., the power to employ a raw material at £2.3 per ton, from which 40 to 50 per cent. of a pulp is obtainable, suitable for all classes of paper; the use of re-agents of little cost; and the production of a solution of the non-cellulose constituents, from which doubtless, valuable products are to be isolated, or which, at least, will cause no detriment to the water-courses into which it may be run, are sufficiently obvious to have already commanded considerable attention from practical men.

The Ekman process differs from the water process, in the sole particular of the presence of the magnesium sulphite; and the function of this salt appears to be, not so much to aid positively in the resolution of the wood, as to prevent the degradation of its constituents in virtue of the reducing activity of its sulphurous acid, and the property of the entire salt of forming compounds with certain of the non-cellulose constituents which enter into solution. In other words, the water, at the elevated temperature at which it is employed, appears to be the effective solvent; but while under ordinary circumstances, the solvent action reaches a limit determined by the formation (by way of oxidation and synthetical combination) of secondary derivatives, which resist the solution, these secondary changes are obviated by the presence of the sulphite and the resolving action of the water is allowed to proceed unimpeded.

Other processes for resolving wood by means of solutions of sulphites have been patented, and worked with more or less success. Upon the exclusively practical question of deciding as to the relative merits of these, it is not for us to speak. We may, however, inquire from what point of view their originators have investigated the matters, and therefore, so far as a study of their specifications will permit, to what extent they contribute to the establishment of the general principle upon which they proceed.

In 1860, Tighman patented a process for the preparation of paper pulp from wood, by heating with sulphurous acid solution, with or without a base, and at a pressure not exceeding that of the atmosphere. In his specification he builds upon two properties of this

re-agent as especially contributing to the result, viz:—(1) Its bleaching action upon vegetable as upon animal tissues; and (2) its specific action as an acid upon the constituents of the wood. This point of view involves no general theory of the chemical function of the substances operated upon; and the want of success which attended Tilghman's work is referable partly to their somewhat inadequate conception of the theoretical basis of his process. Augustus Mitscherlich took out in 1874 a German patent for treating wood with a solution of bi-sulphite of lime, and his process has met with considerable success. This chemist, in his specification, wisely avoids theoretical matters; at the same time, from the statement which it contains that the yield of cellulose from *Pinus Sylvestris* amounts to 60 per cent. of the weight of the wood, we are enabled to gather (1) that he effects a very incomplete resolution of the wood substance, not much more, indeed, than by means of water at the same temperature as that employed by him; and (2) that he attaches a very different meaning to the term cellulose from that which is current amongst chemists who have investigated this subject from the more purely theoretical point of view. We cannot see, therefore, that either of these processes was instituted upon a clear recognition of the chemical relationship of the re-agents. The process also, which bears the name of Francke, is one which addresses itself rather to the main practical end of converting wood into paper pulp than to the establishment of a general principle, and, therefore, can only claim from us this passing notice.

Whatever be the minor issues of these several processes in their competition one with the other, they all offer a solution of the problem of preparing paper-pulp from wood under reducing conditions, and constitute, therefore, together with the many obvious points of superiority of the products, both soluble and undissolved, and of its results, economically considered, a very strong indictment of the older methods; added to which, confirmatory evidence drawn from the theoretical investigations of the constitution of lignified tissues, makes the case for the sulphite method complete.

We must not omit to notice that there has been hitherto a practical objection to this process, which has been of sufficient weight to deter many from adopting it, who were on other grounds fully satisfied as to its superiority—this lay in the necessity of using a lead-lined jacketed boiler, a very costly piece of apparatus in the first instance, and one very liable in the next place to get out of order by displacement of the lining, and thus to cause serious interruptions. It has only recently become known to those engaged in developing this process that a metal has been in use now for several years, in the process of manufacturing glucose, which resists the action of dilute sulphuric acid boiling under pressure, and fulfils all the conditions demanded by the sulphite process for wood-pulp. Its adoption removes the only serious objection which could be urged against the many advantages which it offers.

In the ensuing discussion, the Chairman said Mr. Cross entitled his paper "Technical Aspects of Lignification," but it was mainly directed to the set of changes which occurred in "delignification." The point mainly to be discussed was the success of the various processes to which he had referred for converting such a very common and cheap material as ordinary wood into paper. The chief questions of interest were the character of the fibre produced by the various processes, the yield, the cost, and the use made of the sulphites to which the author had alluded. Although, no doubt, sulphites generally would exercise a protecting action chemists knew that often very minute differences, such as would exist between the various sulphites, might be of most material importance in cases of this kind.

Mr. George Fry said there was one point to which Mr. Cross had not referred, on which he might say a word. He wanted to satisfy himself some years ago that the chlorine process was actually a process of oxidation; he therefore made the following experiment. He treated wood with water at high pressure, and after washing the fibre thoroughly, obtained the brown pulp shown on the table; he then took this pulp and treated it with a dilute solution of nitric acid, and warmed it gently; he thus got an oxidation of the brown colouring matter by the decomposition of the nitric acid. He then treated the pulp with an alkali, and washed away that part of the encrusting matter which was soluble, and by repeating the process several times, got at last a cellulose which was virtually pure but not white; it was a grey colour: under the microscope it appeared colourless; and in order to produce the white colour shown in the other specimen it had to be treated with chlorine. That was an interesting experiment, as showing clearly that the solubility of the encrusting matter was purely due to oxidation. As to the yield of pulp by the different processes, Mr. Cross had told them that if wood were boiled with a caustic alkali, at high pressure, you got, in the main, a yield of 33 per cent. He was interested to see the result if he first boiled the wood in water at high pressure and afterwards treated at the high pressure with caustic alkali; he should have obtained the same quantity of cellulose which he would have obtained if he had treated the wood direct with the caustic alkali, but he found to his surprise that the yield obtained was considerably less, being not more than 25 or 26 per cent. By the present process, however, they obtained a yield of something like 48 to 50 per cent. He was, therefore, of opinion that in both the alkali process, and in the process of first boiling with water, and then treatment with alkali, there was a solution of the cellulose in some way or other.

The following letter on the subject of Mr. Cross's lecture on "Lignification," appears in the *Society of Arts Journal* for the 9th February:—

"I regret much that I was unable to be present at Mr. Cross's lecture, the report of which I have read with great interest, as the subject discussed will, without doubt, have a most important influence on the future of our paper trade. Mr. Cross referred to me as originating the process of boiling under pressure with caustic

soda as applied to esparto; this is not correct, as none of my several patents specify high pressure, but the contrary; neither have I employed high pressure since the introduction of esparto to the trade in 1881, up to the present time, during which I have been treating from 120 to 160 tons of esparto weekly. Indeed, I do not consider that high pressure is required for the treatment of esparto or fibrous materials of a similar character; and although I am aware that high pressure is employed by some paper-makers, its advantages are very questionable; certainly as good results are obtainable by low or atmospheric pressure. The case is different with wood and other vegetable substances of several years' growth, which demand more energetic solvents, and more elevated temperature, only obtainable by high pressure. Mr. Cross referred to Tilghman's patent of 1866, as heating with sulphurous acid solution with or without a base, and at a pressure not exceeding that of the atmosphere. This is not quite correct, as, in the specification of that patent now before me, Tilghman claims "treating vegetable substances, which contain fibres, with a solution of sulphurous acid in water either with or without the addition of sulphites, heated in a close vessel under pressure," &c., and in the body of his patent, he specifies boiling in a closed vessel, heated by means of a steam-jacket, until the temperature of the liquid (sulphurous acid and sulphite of lime) is about 250° Fahr. (=35 lb. pressure.) In 1876, Tilghman took out another patent, claiming the use of sulphurous acid in water under pressure not exceeding that of the atmosphere, stating that the addition of sulphite of lime, magnesia, or soda, or other suitable base, so as to form an acid bi-sulphite, is advantageous. Both these patents of Tilghman's have expired, but a Frenchman, M. Lioud, took out a patent in 1877, for the treatment of woody and textile fibrous materials, with solutions of sulphurous acid, either alone, or more or less combined with different bases, and at a temperature more or less elevated and prolonged. This patent, however, was allowed to lapse, assuming finding he had been anticipated by Tilghman. Now we have Mitscherlich's patent, 1874; Francke's, October 1881; Ekman's, Nov. 1881—all claiming similar processes to the above, and we have, it would appear, to choose between these acid and the caustic soda processes, the latter patented by Houghton in 1857. We have excellent pulp made from wood by the caustic soda process, and it remains to be proved whether that produced by the acid process is equally good, and can be as readily produced with no drawbacks or disadvantages. Wood pulp will certainly extend in use as a paper-making material, seeing that esparto, on which we now mainly rely, maintains its price, and is likely to become dearer.

"THOS. ROUTLEDGE

"Claxhough, Sunderland, Feb. 6, 1883."

NEW PRODUCTS IN THE LOW COUNTRY OF CEYLON.

GENERAL REPORT FOR JANUARY, 1883.

Liberian Coffee—Cocoa—Nutmegs—Cloves—Rubber—Teak—Gamboge—Fruit—Sago—Pepper—Tea.

THIS has been on the whole a dry month, though a few showers fell at intervals of ten days. About the middle of the month, the strong land-wind ceased, and it has since been calm and occasionally cloudy.

The variety of coffee that suffered most from the H. V. is throwing out many suckers from the stem, but nothing on the bare branches, while every leaf, as it expands, becomes the prey of the pest. Such trees as have been only partially denuded of leaves are throwing out secondaries, but with the same result—every fresh leaf becomes infected. Such as came out of the epidemic with little damage have taken a fresh start of regular growth, and promise well, if they can only weather the next storm of spores. The largest blossom of the season was out on the 22nd, and has all set. Of course there was none on the entirely denuded trees, but on the partially denuded it was full, and on the least smothered very large: that is to say, there is as much crop as can be packed on the tree.

The cocoa is recovering from the effect of the wind, but many of the trees still look bare and ragged. When the tree, however, has weathered through the first two years, it seems to have acquired a fund of vitality that rapidly repairs any damage sustained from the weather, unless the soil is too poor, or the situation too bleak, to permit them to get into form at all. Even in such situations, if they survive the first eighteen months, they do not die outright, but continue struggling, and sending up fresh stems, as the old ones wither, till a spell of favourable weather enables them to branch, and then it is safe to become a tree. As soon as the stem is surmounted by a crown of branches a foot long, it comes on with a rush, adding six inches to the length of the branches at every monthly flush, till checked by unfavourable weather. I have three-year-old trees here that completely shade a circle twelve feet in diameter, and, in one case, the first crop is seventy well-established pods, and so little does the tree feel its work that suckers have to be stripped from the stem almost weekly. There are fresh trees coming into bearing weekly, and, as I said last month, there will be an appreciable crop twelve months hence. I begin to believe in this product. In a carefully selected soil, and exposure, we may safely calculate on five hundred weight per acre, on the average of years. This, at 80s., gives 400s. = Rs. 240. The most liberal cultivation and all other expenses of bringing to market would be amply provided for by Rs. 120, leaving Rs. 120 as the profit for the proprietor. After encountering the enemies of the plant, termites, crickets, a species of caterpillar, and a minute insect that preys on the young leaves and tender bark, we have now to make the acquaintance of the foes of the fruit. So far I have only met

with two. One day, I found five ripe pods on one tree and two on another, with the husks torn open, and the seed abstracted. At first I thought it had been a thief, of the genus *homo*, variety *Sinhalese*, but on reflection I came to the conclusion that a human thief would not have sought the least accessible spot in the property, when he could serve his purpose equally on easier ground. Moreover he would not have torn the husk open, with his teeth, or nails, leaving the empty shell on the tree, when he could have carried it off bodily, with so much less trouble. Finding this solution untenable, I had to choose among flying-foxes, squirrels, and crows, and I have not yet settled the point, but a couple of squirrels were seen disporting themselves among the rocks suspiciously near the scene of plunder. The other enemy is a small worm that eats through the husk and enclosed seed before it is quite ripe. I have only found one pod so perforated, but that was utterly ruined.

Since the dry weather came, the few cardamom plants I have took a start, and are now growing rapidly. It seems after all to be that rain was the retarding element.

A nursery of 800 nutmegs produced 240 plants, one-half of which are probably males, and can only be eliminated, after flowering, at the end of four or five years. I am however encouraged to extend this cultivation from the large crop this tree yields after the fifth year, and the promising condition of a few plants on another place.

I have a few clove plants down, but in this dry weather the growth is very slow, but most of them look healthy.

The rubber trees are taking a rest during this dry season. I had a good crop of seed, but when I set about collecting it off the ground, I found that some one had been there before me. I have made enquiry, but have found no clue. I had no suspicion that any one would touch it, but after the deed was discovered I recollected that Rs. 10 per thousand is still demanded in some quarters, and, perhaps paid. So I ceased to wonder why Sinhalese villagers or estate coolies should desire to possess it.

I have land ready for a pinery, and only wait for a few showers to get plants of the best kinds. At the tropical garden, a Kew pine of 19 lb. has been achieved on indifferent soil, and from the very superior appearance of the few plants of this kind I possess, I expect still better results. Of all the fibre plants with which I am acquainted, that of the Kew pine is the finest and the strongest—far too valuable for paper stuff, but especially suitable for the manufacture of thread or linen of the finest quality. In any mechanical process of extracting the fibre from the fresh leaf, the waste would be enormous, but, if Ekman's process can be applied on a smaller and less costly scale than that needed for a large paper mill, a vast trade could be created under the auspices of a local limited company in a couple of years. The quantity of fibre-yielding material in any circle of ten miles radius that goes to waste in the low country of Ceylon would keep a factory at work without any special planting for the purpose. The promoting of a company is not in my line, but I bestow the idea on the public gratis, and I hope it will be taken up by some one, with the necessary qualifications of personal influence and business habits.

Of timber trees, teak grow freely for the first two years, but it is growing little or none now. Certain insects so utterly destroy the leaf, that many of the trees are mere bare poles. In rapid growth the teak beats every other tree. In fresh land of fair quality and not on a severe exposure, it makes one foot in height every month, till it reaches about ten, when it begins to spread out, and the rate of ascent diminishes. I think *halimilila* is a valuable timber and a good shade tree. On the land now clearing there is much *milila*, mostly of so great age. I am trying to save all the straight stems for shade.

Can you tell me if the gum of the goraka tree is the true gumboge and what the value of gumboge is in the market? I will send a sample for report as soon as I can collect enough.

Of fruit trees, the most flourishing I have here is the rambutan. Some thirty plants put in the field are growing very vigorously. The nam-nam plants have all perished but two, and they are not promising. Of some hundreds of oranges I planted, about twenty have outstripped the destructive agencies to which the young plants are so subject. Many other native fruits that I have sown or later failed from a variety of causes, the chief of which are insects and wind. It looks as if the bread-fruit would do well here, in sheltered spots, judging from the one plant that has already become a tree.

The sago palm seed has not germinated well. Indeed very few have grown beyond those that were germinated in the box when they arrived. I will possibly have 100 plants, but I do not know what to do with them, as I have not an inch of the sort of land they are said to require.

After Mr. Holloway's warning about pepper vines I must ascertain whether I have got the best kind. So far as my eye can judge, I can see no difference between what I can get in a neighbouring village for the trouble of removal, and that bearing a high price at the tropical garden, but I must bring the specimens together before extending the cultivation.

The only tea field yet established in this district is on Commilla estate, two miles from here, the property of Dr. Stork, and managed by Mr. A. J. Stork, who has had some years of tea-planting up-country. The field was planted last May, and I can hardly realize a more rapid growth than has taken place, my opinion being just worth as much as that of any other man who has no experience whatever. I believe this is the northern limit of tea cultivation in the low country proper, but it will probably creep northward, as far as the Mahoya, beyond which lies the region of protracted droughts, which seems the one condition likely to check its profitable production. It seems to thrive on all soils and in all temperatures: from sea-level up to the slopes of Pidurutalagala, while the art of manufacturing the leaf is daily extending and improving. Tea seems destined to be a far greater king than ever coffee has been, and with cheap labour, perfect machinery and

ever-increasing skill, Ceylon will be able to hold her own with all the world. As long as the heathen Chinese can poison Christendom with his spurious abomination there will be room in the markets for the genuine article, and the Ceylon planters have always produced the best of whatever they cultivated, and will no doubt continue to do so on a more extended list of products. Ceylon cocoa has already topped the market, Ceylon holds its own with India and Java in cinchona, Ceylon tea is asserting itself, and a multitude of minor products will help to keep the pot boiling. *Hemlena rastaria* has been a sad enemy to the planting interest, but it has not been all evil. Had coffee encountered no more pronounced enemy than the falling fertility of soil, the losing battle would have been fought for a long series of years to come without calling out the reserves and auxiliaries, and the cinchona, tea, cocoa, cardamoms, rubber, &c., would not have been in existence as exported products for many a long year to come. The coffee-leaf fungus is the immediate parent of all the new products that Ceylon is now sending forth, and the planting mind being roused and its energies directed into this channel, there is no discernible limit to the amount and variety of Ceylon's products. Other tropical lands have superior soil, but Ceylon rests her capacity of competition on three facts—a forcing climate, cheap labour, and superior skill.

CINCHONA.

Report of the Sub-Committee of the Planters' Association appointed to communicate with Government on the subject of a series of analyses of Cinchona Barks, in order to obtain reliable data for the guidance of Cinchona Growers.

YOUR Sub-Committee begs to submit its report at the conclusion of its labours, which it regrets have not been successful in achieving the result desired.

It will be in the recollection of members that the following resolution was unanimously passed at a recent General Meeting of the Association, viz.—That this Association, in view of the large and increasing cultivation of cinchona in Ceylon, respectfully requests Government to have a series of analyses of barks made in order to obtain reliable data for the guidance of cinchona growers, and that a Sub-Committee, consisting of Messrs. A. T. Karslake, T. C. Owen, G. A. Talbot, Wm. Forbes Laurie, and W. Smith, be appointed to communicate with Government." Your Secretary immediately forwarded a copy of this resolution to Government, and expressed the hope that it would receive early favourable consideration. No answer having been received to this communication, and it was thought that Government might be waiting for some definite scheme to be laid before it, it was deemed desirable to ask if Government was prepared to accede to the request made, and if so, if it would instruct the Director of the Botanic Gardens to place himself in communication with the Association. In answer, it was intimated that the Governor does not consider that the Government can undertake the work of analysing cinchona bark, and a copy of a despatch from the Secretary of State was forwarded enclosing correspondence with Messrs. Christy & Co., London, complaining of the action of the Commissioners on New Products, and stating that Lord Kimberley has given a distinct assurance that it is not intended to interfere with the ordinary course of trade, and adding that he had no doubt the views expressed were shared by his Excellency. Your Sub-Committee having duly considered the reply received and connected correspondence felt that, however advisable, on general grounds, the decision arrived at in connection with Messrs. Christy & Co.'s complaint might be, it had no necessary practical bearing on the Association's request that Government should arrange for a series of analyses of cinchona bark in order to obtain reliable data for the guidance of cinchona growers. On the contrary, your Sub-Committee maintains that it appeared to militate in no way with the principle laid down by the Secretary of State.

In support of this view, the following reasons were submitted for the consideration of his Excellency the Governor:—

I. That if the Government decides to procure the series of analyses asked for, these analyses will doubtless be made by eminent analytical chemists in the way of their profession, and accordingly that private enterprise will be encouraged rather than otherwise.

II. That when the data desiderated have been obtained by means of analyses, the ordinary operations of commerce will certainly be stimulated. It was further pointed out that your Sub-Committee hoped to be guided by the valuable assistance of Dr. Trimen in the classification of the samples, with a view to enable the Government to lay them before Dr. Paul or some other eminent chemist, and as a further argument for a reconsideration of the subject by his Excellency, the course pursued by the Indian

Government was instanced, and also the present need for every encouragement and help in the prosecution of the enterprise in Ceylon. Your Sub-Committee regrets that on a re-consideration of the question, his Excellency the Governor was unable to reverse his previous decision, and accordingly that for the present at least it must be reluctantly accepted that the Government does not desire to be in any way instrumental in furthering the development of the cinchona planting enterprise in Ceylon on a scientific basis by rendering the assistance asked for, or by affording special help and encouragement to planters in endeavouring to ascertain authoritatively the varieties most likely to be successfully cultivated in various districts, altitudes, and soils.

COFFEE.

COFFEE PROSPECTS.

A CORRESPONDENT of a contemporary writes :—

A review of the present state of the coffee trade would show that it is suffering acutely from the action due to speculation and over-production. Prices have fallen away to the lowest limit compatible with its profitable cultivation. Indeed, there is reason to believe that at 65 shillings per cwt., the price at which M. P. coffee stood a few weeks ago, only the largest, and the best managed, unencumbered estates can work at a profit. Some few years ago large fortunes were made in coffee, in Ceylon, Java, and South America. The public came to know it, and at once there was a rush for the coffee countries. Fancy prices were given for land, extensive plantations were opened, and after a time production was enormously increased. But still, somehow, the demand for coffee kept pace with the supply, trade was good, money was plentiful, the habit of drinking coffee spread, and the price steadily rose. Then speculation ensued; merchants bought coffee for the rise; bankers and houses of agency put their money freely into the hands of planters on the security of land or crops, and a very strong coffee "interest" was established. At the beginning of 1877 coffee prospects were at their brightest, apparently; M. P. coffee touched 121 shillings a cwt.—the high water mark of the coffee rise—double the figure it stood at a short time ago. Ever since, with the exception of a slight rally in January 1880, there has been a continuous fall. The break-down of an American coffee ring, which locked up large supplies in the expectation of a further rise, is said to have had much to do with the fall. Be that as it may, the markets of the world were at length overstocked, a period of general commercial depression followed upon the period of prosperity, in which coffee has shared, money became scarce, speculation in coffee came to a stand-still, and prices fell. With falling prices there came the borer and leaf disease to embarrass the astonished planters; leaf-disease, the chief enemy, existed long before, but had been kept at bay by high and expensive cultivation. Now, diminished crops and falling prices reacted injuriously upon plantations, and leaf disease spread alarmingly. No need to describe the battle with leaf disease. It ended badly. For the most part bravely struggling with adversity, planters without sufficient capital of their own, on bad soils, or otherwise cramped, sank deeper and deeper in—their agents' books. At last the day of reckoning came; in many cases too long delayed. Then it was found that capitalists had been throwing good money after bad, and in the hope of averting bad debts of comparatively small amount, had incurred serious losses. Not only houses of agency, as they are called, but old and solid banks felt the pinch, and hundreds of shareholders, innocent of all knowledge of coffee, felt it in diminished dividends and sunk capital in their houses far away. All this was not calculated to improve the market price of coffee. Investors of all kinds gave it a wide berth, and down it tumbled from bad to worse in spite of the full demand which subsequently arose. It was not leaf disease which cast down the market price of coffee; although that statement is often made. The more leaf disease there is, the scarcer and dearer coffee must become. But indirectly it confirmed the fall by ruining the planter, who, in his turn, crippled the capitalist, who consequently avoids coffee speculation, and will do so until it pays. As will be seen, coffee depression has touched the lowest point. The injurious influences which affected it are temporary in their nature and are passing away; and most important of all, there is no diminution in the consumption of coffee, but rather the reverse.

FORESTRY.

THE FORMATION OF CONCENTRIC RINGS IN WOOD.

UNTIL very recently it was a matter of doctrine to believe that the concentric rings one finds in most woods* constitute each one year's growth. To have questioned the universal truth of this dogma would have been considered the most rank heresy. Even at the present day many writers on forestry fondly cling to the old belief, and this blind uncompromising adherence in every case, in spite of the clearest evidence of contrary facts, to an untenable and exploded theory detracts very considerably from the value of a recently published book, the *Manual of Indian Timbers*, which has obviously cost the writer a vast amount of labour, and is in many respects full of very useful and trustworthy information, both original and compiled.

Recently the *Timber Trades Journal*, in its issue of 11th November last, quoted an interesting extract from the *Canada Lumberman*, giving an authentic instance of the formation of more concentric rings than the number of years in which they were produced. In 1859, a M. Charney caused all the trees to be felled, which hid the façade of one of the pyramids of a palace among the ruins of Palenque in Mexico. In 1880 he again visited the place and cleared the trees that had grown up during the interval of 21 years since 1859, and noticed that of all them contained more concentric rings than their age included years. On the section of one tree, about 2 feet in diameter, he counted 250 rings. "A shrub, 18 months old at most, had 18 concentric circles!"

The extract then goes on to say that Professor Bachelart has asked whether "M. Charney took account of certain coloured rings which some tropical trees present in cross-section, and which are to be distinguished from the annual circles." These lines of different colour, as every one knows, mark the progressive conversion of the sap-wood or alburnum into heart-wood or duramen, and may be seen conspicuously illustrated in many Indian woods, such as, for instance, teak, *Bauhinia thurifera*, &c. They have nothing to do with the production of new wood.

The *Timber Trades Journal* then remarks as follows :—

"If this be so—and it must be observed we have only one witness yet—the learned in arboriculture, ancient and modern, have been at least doubtful, if not false, teachers. And if this deviation from the old rule is peculiar to 'hot and moist climates,' where shall we draw the line? There must be some intermediate stage of average barometrical temperature (*sic*) at which this perplexing change commences in the development of tree growth, or is the whole hypothesis imaginary, and no rule at all?"

"This important question cannot be allowed to remain in its present unsatisfactory state. The account given by M. Charney, as recorded by Professor Bachelart, will have to be either contradicted or confirmed; and a very pretty controversy among adepts, or, as it is now the fashion to call them, experts, is likely to result from it. It seems almost impossible that two theories so opposite to each other can both be true: and, if there be found a connecting link between them, how shall we know to which side of it our specimen may belong? Hitherto these 'concentric circles' in trees were as religiously believed in as the revolutions of the planets. Are we now to unlearn all we have been taught about them?"

As the subject of the above remarks is extremely important, and, as the remarks themselves show, but little understood, I may be pardoned if I venture to contribute towards a better knowledge of it by publishing in the *Indian Forester*, in a condensed form, what information I possess bearing on it. For the sake of clearness, it will be impossible for me to avoid entering into some questions of vegetable physiology.

It is now an established fact that the well-defined line between two adjacent rings of wood is caused by a sudden variation of tension in the growing or other soft tissues along the circumference of the stem.

In the case of growing tissues, tension may be due to one or more of the following four immediate causes :—

I. Turgidity of the component cells due to the hydrostatic pressure of their contents of their walls. This pressure can occur only

* I need hardly say that the stems of tree *Lilacæ*, of many climbers, such as *Bauhinia Vahlii*, *Millettia auriculata*, &c., and of some other angiospermous species do not increase by the addition of continuous layers of wood all along the circumference. An extraordinary mode of growth, which has never been observed before, and which will astonish vegetable physiologists, has been noticed by me in a specimen of *Dalbergia paniculata*, and will shortly be described in the *Indian Forester*.

is generally poor. A few of the best fruits should, therefore, be annually reserved for seed, for sowing in the following season.

KURKEE. (*Cucumis utihaiensis*).—This species of cucumber has fruits from one to two feet long. When in a young state they are covered with soft, downy hairs, and are then of a pale green colour. When fully ripe the colour changes to a brilliant orange. It is a true hot-season vegetable, and will not succeed in the North-West Provinces, at least during any other season. It should be sown in the end of February and any time during March. It prefers a dry, loose, open soil. A well drained plot should therefore be selected for growing it. After manuring, the ground should be laid out in beds, and three or four seeds sown in patches three feet apart. As with vegetable marrows, only one of the strongest should be allowed to remain if they all germinate. Water should be given once in ten days. If given too often the fruits turn yellow and fall off before they are ready for use. February sowings are ready for use towards the end of April. If a second sowing is made about the middle of March, it will keep up the supply until the beginning of the rains.

KHEERA, (*Cucumis sativus*, var.).—This is a variety of the common cucumber, with small egg-shaped fruit, and is also a true hot-season vegetable. In order to keep up the supply until the beginning of the rains, three sowings should be made—one in the end of February, one in the middle, and one in the end of March. It will succeed fairly well in any soil, but prefers a rich one. The ground should be laid out in drills, one foot apart. Sow the seeds along both sides of the drill, and if the soil is very dry, water immediately after sowing. After they germinate, water every ten days. This vegetable, like the *kurkee*, should not be watered too often.

KURRAILA (*Momordica charantia*, var.).—There are two varieties of this vegetable. The natives call one *kurraila* and the other *kurrali*. The former comes into use during the hot season, and the latter during the rains. The greatest difference between them appears to be the season when ready for use, as both are of the same appearance. The fruit is pitted at both ends, and covered with knobby protuberances. It has a very bitter taste: nevertheless, it is much relished by some in curries. It should be sown in the end of February and all through March, in rich soil. The ground should be laid out in beds, and the seeds sown in lines two feet apart, and the same distance allowed between each seed. Water should be given twice a week until the ground is covered, afterwards once a week will be sufficient. The first sowing will come into use about the middle of April, and successive sowings made in March will keep up the supply until the beginning of the rains.

BRINJAL OR EGG-PLANT (*Solanum melongena*).—This is a popular vegetable with native gardeners, and one of the most useful. It is almost needless for me to describe its cultivation in detail, as they seldom fail to grow it to perfection. It can be brought into season at any time, and this quality causes it to be very valuable when other vegetables are scarce. It should be sown in October and November when required for use during the hot season. It can also be sown in February and March, and will then come into use about the beginning of the rains. It will grow in any soil, but as with other vegetables, thrives best in a rich one. It should be sown in beds and transplanted when two or three inches high, in lines at a distance of 18 inches apart. It should be watered twice a week, and the soil frequently stirred around the neck of the plants. The fruits are very palatable when properly cooked, and no garden should be without them.—W. G.

HOW TO APPLY FERTILIZERS.

MANY orchardists in California are, it seems, awakening to the necessity of maintaining the fertility of their orchards by the application of manures of different kinds, and it will be timely to introduce some facts concerning the method of application. There is a right way and a wrong way, and fortunately the proper method can be shown by a series of systematic experiments. A writer for the *Country Gentleman* gives the following:—"A rule adopted by an old writer gives the length of the roots as equal to the branches above. It is safe to say that this rule does not indicate generally more than a tenth of the ground which the entire roots really occupy. Many years ago I made an experiment on a row of peach trees planted in grass and within a few feet of each other. They had been set three or four years, and were eight or nine feet high. Within a few feet of one end of the row the ground was made very rich with a heap of manure. Its stimulating effect upon the nearest tree was such that the shoots made in one season were two feet and a-half long. The

tree, which stood seven feet from the manured ground, made shoots fifteen inches long, and at eleven feet distance the shoots grew seven or eight inches. At fifteen feet no perceptible effect of the manure was visible, the growth not exceeding three inches. The experiment showed that a decided benefit was gained to the tree at eleven feet distance through the few roots on one side, and that the roots formed a radiating circle at least twenty-two feet in diameter.

MINERALOGY.

THE most important result of the past season's work, says Mr. H. B. Medlicott in the February part of the *Records of the Geological Survey of India*, has been the proving of the new coal field of Umaria at the west end of the South Rewah-Gondwana basin, within 34 miles of Katni station on the East Indian Railway. This field was mentioned in the last annual report, and Mr. Hughes had given a notice of it in the *Records* for 1881 (vol. XIV, part 4). The actual area of exposed coal measures is small (about 3 square miles), in an angle between the gneissic rocks and the great spread of newer Gondwana sandstone to the north-east. The out-crop of coal had been known for many years, but its appearance at the surface was not promising. All this area had been surveyed in 1872 by Mr. Hackett, without distinguishing the true coal measures; but, from what I had seen of the ground (in March 1869), on a preliminary inspection between Raneegunge and Jubbulpore, I was aware that further examination would be necessary before anything could be published. Mr. Hughes's success was then no chance find; he recognised a difference between the Umaria sandstone and that of the adjoining area, and he had a close search made for fossils, from the evidence of which there was no longer any doubt of these rocks being on the horizon of the regular coal measures. He then at once marked sites for trial borings; and these were carried out with very commendable expedition by the local authorities. The results, as to the extent, thickness, and quality of the coal, are very promising. A notice of these borings was given by Mr. Hughes in the *Records* for August last. Railway surveys are now being made for a line from Katni to the coal-field.

The field thus opened to enterprise is very extensive. Umaria is the nearest possible source of coal for the North-Western Provinces; and immediately east of it lies the immense coal-field of Sohagpore, which district is also rich in agricultural produce and the natural entrepot for the surrounding forest tracts. From Sohagpore southwards lies the least difficult line of communication between Northern and Southern India, into the plains of Chutteesgurb, leading down the Mahanuddy valley to Cuttack, and up it over the plateau of Bastar to Vizagapatam.

Not the least important result of this new opening is the opportunity it gives for successful iron manufacture. I know of no spot in India where there is such an abundant supply of a variety of first-class iron ores as in the neighbourhood of Katni. Much of the lime now used in Calcutta comes from Katni, and other requisites will probably be forthcoming, if the coal fulfils our expectations.

Mr. Hughes extended his survey of the Sohagpore coal-field eastwards into Sirgajah. He reports in very encouraging terms of the services rendered by sub-assistant Hera Lal.

In the Annual Report for 1877 (Rec. XI, page 7), a notice was given of the explorations for coal in the Satpurah region, carried on by the Central Provinces Government under my advice, and the concluding operations of those trials are given at page 97 of the *Records* for 1879 (vol. XII). Most of those trials were near the northern edge of the basin close to the Nerbudda valley, and four of them were in interior valleys. In every case the object was to find the coal measures themselves, for the borings all started in rocks known to be of later formation, and in one case only, that close to Mahpani, was there an outcrop of the coal measures anywhere near. None of them were successful; and it was then pointed out that the nearest ground where there was a direct prospect of coal was in the Shalpur field on the south side of the basin. The outcrops there had been reported on separately by three officers of the Survey (in 1859, 1866, and 1875), but none held out any promise of valuable seams. The latest of these surveys was by me (published with a map in vol. VIII of the *Records*), and I then marked three sites for borings in different parts of the field, in view of future experimental exploration. These trials were taken up in February 1881, by the Public Works Department of the Central Provinces, and the last of them was closed on the 11th of October 1882 under my instructions. Two of them were made to a depth of 400 feet, and the third to 539 feet. They all passed through several coaly seams,

with some thin bands of coal; but none were of sufficient promise to recommend the sinking of a trial shaft. I believe that all the coal-bearing measures were passed through in each boring, but the seams are even poorer than at their outcrops. The coal prospects in the Satpurah basin are thus for the present reduced (besides the Mahpani mines) to the Pench valley field, of which Mr. Blanford gave a very encouraging report in 1866 (*Records*, vol. XV, part 2, 1882). This field has naturally been left to the last on account of its comparative inaccessibility; but the engineering difficulties to be overcome are nothing like so great as those on the new Indore and Bhopal State Railways, and a line from Itarsi up the Tawa valley to the Pench would be in every respect the most favourable for crossing the Satpurah range between the Nerbudda valley and Nagpore. Such a line would pass along the Shahpore coal field, and might lead to a further exploration of those measures.

The cretaceous coal-field of Darangiri in the Garo Hills, reported on by Mr. LaTouche (*Records*, Vol. XV, part 3) during last season, proved quite as good as was expected; the quantity is very considerable and the quality very serviceable; but if the company now engaged in opening out the coal-fields of Upper Assam achieves anything like the service it proposes, it would scarcely pay to work the much inferior coal of Darangiri. Mr. LaTouche is now engaged in tracing the coal of the Jaintia hills eastwards, with reference to a project for a railway through North Cachar.

Mr. Foote was engaged in the districts of Madura and Tinnevely, principally in completing his map of the coastal region, and joining this work with that of Mr. King in Travancore. The principal features of the ground had been examined in previous seasons, so there is nothing particular to be noticed. A detailed account of this large area will be published during the current year. Late in the season Mr. Foote made a traverse across part of the Mysore gold-fields, an account of which is published in the *Records* for November.

SERICULTURE.

MAJOR COUSSMAKER has concluded his experiments in tussar sericulture, and the result arrived at is a contemporary says, not such as to encourage the hope that it can be made a paying industry in the Bombay Presidency. The direction in which Major Coussmaker's efforts were chiefly directed was towards the production of "tusser waste," which term signifies the silk taken from the burst cocoons after the moths have flown. He found the expense, either of collecting the cocoons from the forests or of rearing them in a state of semi-domestication, to be so great that no margin of profit is left upon their sale to the manufacturers in England. The cocoons cannot be collected from the forest, it appears, at a less cost than four annas per hundred; and as regards the attempts at cultivation, though the results were most satisfactory as to the quantity produced, the outlay required for watering the shrubs, protecting the worms and cocoons from crows, sparrows, squirrels, rats, &c., was again too high to admit of any profit. The tussar cocoons of the Bombay Presidency are smaller and contain less silk than those found in other parts of India, and all Major Coussmaker's efforts to increase their size proved abortive, the climate, he finally concludes, being an unsurmountable obstacle. Major Coussmaker sent home 197 lbs. of cocoons which he had collected during two years, and they realized only Rs. 146 14 annas, China is now exporting wild silk so largely that the price of tussar waste in England is only 1s. 3d. per lb. During the last year of his experiments Major Coussmaker was able to collect and produce 25,031 cocoons, weighing only 57½ lbs., and the amount expended to obtain this result was Rs. 168-13-9. Major Coussmaker has handed over his plantation of Lagerstrœmia and Ziziphus bushes, together with the bamboo screens, iron rods, &c., he used for enclosures, to the Superintendent of the Yerowda Jail, as there is land attached to the jail, in which the bushes can be planted, and the head jailor takes an interest in the experiments. Major Coussmaker adds:—"A very little expenditure in water labour will suffice to keep the plants in good health, and, as they will continue growing, will be available for any future experiments which may be made. If no other use be made of them, they can be planted as hedges in the garden, and as they bear a profusion of beautiful lilac flowers, and when kept trimmed break most luxuriantly into leaf, they will form an ornamental, as well as an useful, addition to the gardens."

GOVERNMENT

CHINCHONA FEBRIFUGE.

AN efficient substitute for Quinine. Sold by
A and Native Druggists of Calcutta. Obtainable from the
Superintendent, Botanical Gardens, Calcutta. Post free, at 40s.,
Rs. 6; 50s., Rs. 11; 16 oz., Rs. 20-12. Cash with order.

PLANTERS' STORES & AGENCY CO., LIMITED,

MERCHANTS AND GENERAL AGENTS,

Calcutta.—30, STRAND.

General Manager—W. E. S. JEFFERSON.

Manager—

Agencies for Tea Estates undertaken on the most
advantageous terms.

Coolies recruited by our own staff of experienced Agents, with
Depôts throughout Chota Nagpur and at Dhubri.

Indentors and Consignees of all merchandise,
Army, Navy, Civil Services, and Private Agents.

Assam.—"THE EXCHANGE," DIBRUGARH.

de Chabrol, Paris, France. 447

THE GREAT REMEDY FOR PRICKLY HEAT, INDIGESTION, HEADACHE, BILIOUSNESS, AND FEVERS.

The testimony of medical authorities has been unqualified in praise of

LAMPLOUGH'S PYRETIC SALINE,

As possessing elements most essential for the restoration and maintenance of health with perfect vigour of body and mind.
It is Effervescent and Tasteless; forming a most Invigorating, Vitalising, and Refreshing Beverage.
Gives instant relief in HEADACHE, SEA OR RIBBON SICKNESS, CONSTIPATION, INDIGESTION, LASSITUDE, HEARTBURN, and FEVERISH COLIC; prevents and quickly cures the worst forms of TYPHUS, MALARIA, JUNGLE, and other FEVERS, SMALLPOX, CHOLERA, and ERUPTIVE or SKIN COMPLAINTS, and various other altered conditions of the blood.

Dr. FROST—"Unfolding source of immense benefit to mankind."
Dr. MONAGHAN—"It purifies the blood with its best saline constituents."
GOVERNMENT OFFICIALS AND PLANTERS caring for the welfare of their employes should note its value as a specific in Fever cases.

Dr. J. W. DOWLING—"I used it in the treatment of forty-two cases of Yellow Fever, and am happy to state I never lost a single case."
Dr. W. F. BARNES—"Since its introduction the Fatal West India Fevers are deprived of their terrors."
SIR WILFRED'S REPRESENTATIVE the GOVERNOR OF SIERRA LEONE in a letter of request for an additional supply of the Pyretic Saline, states—"It is of great value, and I shall rejoice to hear it is in the houses of all Europeans visiting the tropics."

To be obtained of any Chemist or Drug Store, in Patent Glass-stoppered Bottles, 2s. 6d., 4s. 6d., 11s., and 21s. each.
Please note in connection with the recently observed effects of the use of Citrate and other preparations of Magnesia that LAMPLOUGH'S PYRETIC SALINE is warranted not to contain any substance which would cause calcareous or other earthy deposits.

H. LAMPLOUGH, 113, HOLBORN HILL, LONDON, E.C.

ZULULAND AND CETEWAYO.

"I know what it is," he answered; "this honey is made from euphorbia flowers, which are very poisonous." This explanation made me feel exceedingly uncomfortable; but I elicited from him that there was not much danger, as the 'maass' taken with it would neutralise the effect of the poison. Directly he mentioned poison I dived into the packs, and pulled out a bottle of ENO'S FRUIT SALT, and emptying a quantity into two pannikins, filled them up with water, and several times repeating the dose, in a few hours we were considerably better."
"Zululand and Cetewayo," (p. 139), by Captain W. R. Ludlow, 1st Batt. R. V. Royal Warwickshire Regiment.

"What on earth shall I take to Zululand?" asked my friend Jim Law one day at Aldershot, when he had just received orders for South Africa, to start at forty-eight hours' notice. I replied, 'If you take my advice—and it's that of an old traveller—you'll not budge without a few bottles of ENO, even if you leave half your kit behind. I never am without these Salts, and, please the pigs, never intend to be.' On his return I inquired, 'Well, how about ENO'S FRUIT SALT?' 'My dear fellow, it was the best advice you ever gave; they saved me many an illness; and when I left Tugela, I sold the remaining bottles for ten times the original price!'—Lieut.-Col.

JEOPARDY OF LIFE. THE GREAT DANGER OF DELAY.

You can change the trickling stream, but not the raging torrent.

WHAT EVERYBODY SHOULD READ.—How important it is to every individual to have at hand some simple, effective, and palatable remedy, such as ENO'S FRUIT SALT, to check disease at the outset! For this is the time. With very little trouble you can change the course of the trickling mountain stream, but not the rolling river. It will defy all your tiny efforts. I feel I cannot sufficiently impress this important information upon all Householders, or Ship Captains, or Europeans generally, who are visiting or residing in any hot or foreign climate. Whenever a change is contemplated, likely to disturb the condition of health, let ENO'S FRUIT SALT be your companion; for, under any circumstances, its use is beneficial and never can do harm. When you feel out of sorts, yet unable to say why, frequently without any warning you are suddenly seized with lassitude, disinclination for bodily or mental exertion, loss of appetite, sickness, pain in the forehead, dull aching of back and limbs, coldness of the surface, and often shivering, &c., &c.; then your whole body is out of order, the spirit of danger has been kindled, but you do not know where it may end: it is a real necessity to have a simple remedy at hand that will answer the very best end, with a positive assurance of doing good in every case and in no case any harm. The pilot can so steer and direct as to bring the ship into safety, but he cannot quell the raging storm. The common idea when not feeling well is, "I will wait and see, perhaps I shall be better to-morrow;" whereas, had a supply of ENO'S FRUIT SALT been at hand, and use made of it at the onset, all calamitous results might have been avoided. What dashes to the earth so many hopes, breaks so many sweet alliances, blasts so many auspicious enterprises, as untimely death?

ENO'S FRUIT SALT.—"After suffering for nearly two and a half years from severe headache and disordered stomach, and after trying almost everything and spending much money without finding any benefit, I was recommended by a friend to try ENO'S FRUIT SALT, and before I had finished one bottle I found it doing me a great deal of good, and now I am restored to my usual health; and others I know that have tried it have not enjoyed such good health for years.—Yours most truly, ROBT. HUMPHREYS, Post Office, Barnsford."

SUCCESS IN LIFE.—"A new invention is brought before the public, and commands success. A score of abominable imitations are so immediately introduced by the unscrupulous who, in copying the original closely enough to deceive the public, and yet not so exactly as to infringe upon legal rights, exercise an ingenuity that, employed in an original channel, could not fail to secure reputation and profit."—ADAMS.

CAUTION.—Legal rights are protected in every civilised country. Examine each Bottle, and see the capsule is marked "ENO'S FRUIT SALT." Without it you have been imposed on by worthless imitations. Sold by all Chemists, price 2s. 9d., and 4s. 6d.

DIRECTIONS IN SIXTEEN LANGUAGES HOW TO PREVENT DISEASE.

Prepared only at ENO'S FRUIT SALT WORKS, HATCHAM, LONDON, S.E., by J. C. ENO'S Patent.

PHOENIX IRON WORKS, CALCUTTA.

THE OLDEST ENGINEERING ESTABLISHMENT IN INDIA,
JESSOP & CO.,

Civil and Mechanical Engineers, Contractors, Brass and Iron Founders,
Metal Merchants, &c.

*Forged and Cast Iron Work, Boilers, Machinery for Jute, Cotton and Rice Mills, Collieries, Indigo Concerns, Tea Gardens, &c.,
Contractors' and Brick-making Plant, and every class of Iron and Brass Work made to order.*

SOLE AGENTS FOR

Robey & Co's celebrated Portable and Fixed Engines and Machinery, Gwynne & Co's "Invincible" Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

IMPORTERS AND MANUFACTURERS OF EVERY DESCRIPTION OF STEAM ENGINES AND MACHINERY.

Robey & Co's Portable, Horizontal, Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand, Lift and Force Pumps, Tangye's "Special" Steam Pumps, "Vauxhall" Donkey Pumps, Flour Mills, Soorkes Mills, Pug Mills, Brick-making Machines, Road Rollers, Saw Benches, Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines, Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selkirk's Boiler Tube Benders, Steam Pressure Recorders, Electric Pens, Richard's Engine Indicator, Gifford's Injectors, Cooking Stoves, Fire-Proof Safes.

The following are the principal advantages of the "Invincible" Pump:—

1st.—It is arranged to swivel on the bed plate, and may be placed at any angle simply by slackening a few nuts, without interfering in any way with the bed plate or the joints of either the suction or discharge pipes.

2nd.—It does not require a foot valve, being fitted with small air exhauster and clack on discharge which always keep the pump charged ready for work.

3rd.—The bearings are made on an entirely new principle, and one bearing will last out four of the old arrangements.

J. & H. GWYNNE'S
"Invincible" Centrifugal Pump.

4th.—The form of the pump casing is so arranged that one side can be taken off in a few minutes for the inspection of the whole of the disc and interior of the pump.

5th.—Hand holes are made on each side of the suction pipes to enable any foreign matter which may get into the pump or disc to be easily removed. The covers are fitted with a bayonet joint so that they can be removed and replaced in less than a minute.

6th.—The "Invincible" is 25 per cent lighter than any other Centrifugal Pump in the market, and discharges at least 10 per cent. more water for the power applied.

Ransome's Indian Plough. Price, Rs. 15.

Howard's Ryots' Plough. Price, Rs. 20.

These Ploughs have been expressly designed and manufactured for the use of the Ryots of India, whose special needs have been carefully studied in their construction. They embody all the qualifications for which the native-made implements have hitherto been preferred, whilst being incomparably superior in strength, durability, and efficiency.

MORAE'S PATENT SUB-SOIL AND GENERAL PLOUGH

Stirs up the soil to three times the depth of a native plough, and leaves the good mould on the top. Goes through the dirtiest land without getting choked with weeds. Price, Rs. 15.

INDIGO AND TEA PLANTERS' IMPLEMENTS AND STORES.

ENGINEERS' TOOLS AND STORES OF ALL KINDS.

ALWAYS ON HAND A LARGE STOCK OF PLATE, BAR, ANGLE, TEE AND CORRUGATED IRON, STEEL, BRASS, COPPER, PIG IRON, FOUNDRY COKE, SMITHY COAL, FIRE BRICKS, AND FIRE CLAY.

Catalogues on Application.

GOODALL'S Household Specialities.

A Single Trial solicited from those who have not yet tried these Splendid Preparations.

YORKSHIRE RELISH.

The Most Delicious Sauce in the World.

This cheap and excellent Sauce makes the plainest viands palatable, and the daintiest dishes more delicious. With Chops, Steaks, Fish, &c., it is incomparable. In bottles, at 6d., 1s., and 2s. each.

GOODALL'S BAKING POWDER.

The Best in the World.

Makes delicious pudding without eggs, pastry without butter, and beautiful light bread without yeast. In 1d. packets, 6d., 1s., 2s., and 5s. tins.

GOODALL'S QUININE WINE.

The Best and most Agreeable Tonic yet introduced.

The best remedy known for Indigestion, Loss of Appetite, General Debility, &c. Restores delicate individuals to health. At 1s. 1½d. and 6s. 3d. each bottle.

GOODALL'S CUSTARD POWDER.

For making Delicious Custards without Eggs, in less time and at half the price.

The Proprietors can recommend it to Housekeepers generally as a useful agent in the preparation of a good custard. GIVE IT A TRIAL. Sold in boxes, 6d. and 1s. each.

GOODALL'S GINGER BEER POWDER

Makes Three Gallons of the Best Ginger Beer in the World for Threepence.

The most valuable preparation for the production of a delicious and invigorating beverage. It is easily made, and is by far the cheapest and best Ginger Beer ever offered to the public. Sold in packets, 3d. and 6d. each.

GOODALL'S. EGG POWDER.

Its action in Cakes, Puddings, &c., &c., resembles that of the egg in every particular. One penny packet will go as far as four eggs! and one sixpenny tin as far as twenty-eight. Sold everywhere, in 1d. packets; 6d. and 1s. tins.

GOODALL'S BLANCMANGE POWDER

Makes delicious Blancmange in a few minutes. In boxes at 6d. and 1s. each.

All the above-named Preparations may be had of all Grocers, Chemists, Patent Medicine Dealers, and Oilmen.

Proprietors: GOODALL, BACKHOUSE & CO, Leeds, England.

FREEMAN'S SYRUP OF PHOSPHORUS.

Nature's Great Brain and Nerve Tonic and the most wonderful Blood Purifier. The highest Medical Authorities say that it is the only Cure for Wasting Diseases, Mental Depression, Loss of Energy, and Stomach Complaints.

It is pleasant to the taste, and might be taken, by the most delicately constituted. In the most enfeebled it builds up a NEW AND HEALTHY CONSTITUTION. One dose of this Remedy is equal to Twenty Doses of Cod-Liver Oil.

Thousands have been snatched from the brink of the grave by the timely use of FREEMAN'S SYRUP OF PHOSPHORUS. May be had of all Chemists and Patent Medicine Vendors, in bottles at 2s. 9d., 4s. 6d., 11s., and 33s.

NOTICE.

In ordering through London Shippers, purchasers should be particular to stipulate for
SUTTON'S SEEDS.

TESTIMONIAL.

From S. Jennings, Esq., late Vice-President of the Agri-Horti Society of India.

"With reference to your mode of packing seeds for export, I must say how much I was gratified with the system you were so good as to show me. During the whole of my long Indian experience, it was my constant regret that English packed seeds were almost invariably lower in germinating power than the American. After seeing the elaborate precautions you take in executing such orders as that of the Agri-Horti Society of India, I am by no means surprised to hear that you have been gratified by the receipt of so much testimony from the tropics as to the condition of your Seeds upon arrival."

FOR STEAM, WATER, WIND, CATTLE, AND MANUAL POWER.

Hydraulic and Screw Presses, Oil Mill Machinery, Hydraulic Lifts, &c.

SOLE MAKERS FOR GREAT BRITAIN OF

BLAKE'S PATENT DIRECT-ACTING STEAM-PUMP,—MORE THAN 10,000 IN USE.

THE FOLLOWING ARE SOME OF THE PROMINENT ADVANTAGES OF THE BLAKE PUMP:—

It will start at any point of stroke.
It has no dead point.
It works fast or slow with the same certainty of action.
It is economical. Has a lead on the Slide Valve.
It is compact and durable.

Hand Power Lever Detached.

It is interchangeable in all its working parts.
It will deliver more water than any other Pump.
It is made of best materials in the most workman-like manner.
Can be worked at 200 strokes per hour, or 20 strokes per minute.

Deep-well Pumps, for Horse or Bullock Power.

Vertical Combined Steam Engine Boiler, and Deep-well Pumps.

BLAKE'S PATENT Direct-acting Steam Pump and Boiler Feeder.

Oil Mills, for Steam or Cattle Power.

Double-barrel Contractors' Pumps, for Hand or Steam Power.

Double-barrel Fire Engines, for Mansions, Factories, &c.

Deep-well Pumps for Hand Power.

Melbourne, 1880.

1878.

Cincinnati, June, 1880.

OVER 450,000 FEET SOLD DURING 1881,

- Including 3,877 feet of main Driving Belts, of widths ranging from 13 in. to 60 in., are working in over 6,000 Mills and Works in Europe and America.

The following Tests (by Kirkaldy, of London) show the relative strength and value, compared with Leather.

| | Breaking Strain per Square inch of Section. | Price per foot. |
|-----------------------------------|---|-----------------|
| Best Double Leather 8 in. Belting | 3,572 lbs. | 5s. 7d. |
| Gandy's 8 in. x 8-ply Cotton | 6,811 lbs. | 2s. 6d. |

THE GANDY BELT.

Any Length or Width for Main Driving.

It is the best belt ever made for all purposes. Much Cheaper and Stronger than Leather. Thoroughly Waterproof, and not affected by temperature, clings well to the pulleys, runs true, and can be made any length without joints.

This Series of Belting (see engraving) was supplied in One Order to Messrs John Crossley and Sons, Halifax, May 1, 1880, and continues to give entire satisfaction.

THE "GANDY" BELT.

GANDY'S Patent American Cotton Belting can claim a superiority over leather belts in every particular; its cost is being about half that of leather, while its strength and gripping power is about double that of the best leather, as shown by repeated tests taken by Kirkaldy, of London. These tests are given above, to which special attention is directed. These "Gandy" belts are made of any width up to 72 inches, and any length up to 340 feet without joint, thus obviating the necessity of having two belts on the same pulley, a system of driving which is never satisfactory, and is impossible to have belts of exactly the same tension; hence one or the other is always causing a stoppage. These stoppages are avoided by using Gandy's Patent Belts in one width. These Gandy Belts are made of the finest American Cotton Duck, specially prepared at Baltimore for the purpose, and then put together and finished by Gandy's patented special Machinery and process to prevent stretching and render them impervious to atmospheric influences. Possessed of advantages such as these, the universal adoption of Gandy's Belts can only be a question of time.

A SUBSTANTIAL GUARANTEE GIVEN WITH EVERY MAIN DRIVING BELT.

HEALTH, STRENGTH, AND ENERGY.

DR. LALOR'S PHOSPHODYNE.

(Trade Mark—Phosphodyne.)

TWENTY YEARS' PUBLIC TEST, AND THOUSANDS OF TESTIMONIALS FROM

ALL PARTS OF THE WORLD ESTABLISH

PHOSPHODYNE

as the only Safe, Reliable, and Never-failing Phosphoric Remedy for Over-worked Brain, Sleeplessness, Harassing Dreams, Worry, Anxiety, Excitement, Epilepsy, Business Pressure, Wasting Diseases, Nervous Prostration, Stomach and Liver Complaints, Impoverished Blood, Premature Decay, and all morbid conditions of the system dependent upon the deficiency of the Vital Forces.

DR. LALOR'S PHOSPHODYNE PURIFIES AND

Enriches the Blood, Clears the Skin, thoroughly Invigorates the Brain, Nerves and Muscles, Re-energises the Failing Functions of Life by supplying the PHOSPHORIC element which has been wasted, and thus imparts Energy and Fresh Vitality to the Exhausted Nervo-Electric Force, and rapidly Cures every form of Nervous Debility, Paralysis, Kidney, Nervous, Mind, and Heart Diseases, from whatever cause.

This elegant Phosphatic combination, the Wonder of Modern Chemistry, is pronounced by the most eminent members of the Medical Profession to be unequalled for its power in replenishing and elaborating the Vitality of the Body; by its supplying all the essential and vitalising constituents of the BLOOD, BRAIN, and NERVE SUBSTANCE; and for developing all the Powers and Functions of the System to the highest degree; by its being agreeable to the palate, and innocent in its action. While retaining its wonderful properties, it acts as a Specific, surpassing all the known THERAPEUTIC AGENTS of the PRESENT AGE, for the SPEEDY and PERMANENT CURE of the above disease.

DR. LALOR'S PHOSPHODYNE is sold in Bottles at 4s. 6d. and 11s. by all Export, Wholesale, and Retail Medicine Vendors throughout the World.

IMPORTANT NOTICE.—NONE IS GENUINE UNLESS the name, Dr. Lalor's Phosphodyne, London, England, is blown in the Glass of each Bottle, and every Bottle bears the British Government Stamp, with the words DR. LALOR'S PHOSPHODYNE, London, England, engraved thereon by Order of her Majesty's Honourable Commissioners; IF NOT, IT IS A FORGERY, AND YOU HAVE BEEN IMPOSED UPON BY A WORTHLESS IMITATION.

MANUFACTURED ONLY AT THE

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah in particular varies so much in the different provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

A UNIVERSITY OF THE ALLIED SCIENCES.

TO THE EDITOR.

SIR,—Hitherto no college or school, where the allied sciences are taught, has made, in connection with the universities, provision for conferring distinctions and honours to their different grades of students. To my mind this should, for progress, be made as early as practicable. New university certificates and titles, hitherto unknown and uncoined by the university members, should be coined, established, and conferred. There need be only one certificate, that of the *Licentiate of the Allied Sciences*, to be conferred on students who have finished three years' course of the School Department; three College Department titles, viz., B.A. Sc., Bachelor of Allied Sciences, to be conferred on students who have finished the first two years' course in the College Department; M.A. Sc., Master of Allied Sciences, on finishing the next two years' college course, and D.A. Sc., Doctor of Allied Sciences, on finishing the last year college course:—altogether eight years' course—three years in the School Department, and five years in the College. Only students (candidates) sufficiently advanced in English literature, or literature belonging to any other language as applied to other countries where English is not the national or country's language, to be able to understand science, should be eligible for admission in the last class of the school department. If candidates have received a course in some college of general culture up to the end of the second university certificate known as *Licentiate in Arts*, they should be considered eligible for admission in the last class of the school department.

The real reason of, hitherto, no certificates and titles conferred by the universities on the students of allied sciences is the ignorance of the great importance of the science of plant-culture by the university syndicates and faculties in all parts of the world; especially this is applicable to India. On the subject of certificates and titles herein referred to, the students of the Sydapet School of Agriculture in Madras applied to the Madras Government, which application proved futile, owing to two causes: the first is that described above, and the second is that the students (School of Agriculture) being wanting in sufficient learning to deserve university certificates and titles.

Since the course now in vogue for the tuition in the allied sciences is both meagre and defective (because no proper encouragement is in store for the students), reformation of the existing state of things assumes paramount importance. I will record my views on the subject as described under:—

The existing Colleges and Schools of Agriculture, Forestry, Medicine, and Engineering, also Veterinary (wherever existing),

now existing as altogether separate educational institutions, should be united and denominated the *United Colleges of the Allied Sciences*, established and located in the same place (any suitable locality) and within one spacious building or buildings, but adjoining each other, if one building be found unsuitable. The building or buildings should have apartments for school and college classes, laboratories, dissecting-rooms, hospitals and dispensaries, library, and office, with sufficient appendages for workshops, land for botanical garden, farm, orchards, &c., and quarters for professors, teachers, and resident students, also sheds and quarters for garden and farm animals and superintendents and resident gardeners. There need be no principal or principals in the united colleges, but only professors for college classes and assistant professors for the school classes. Students of all denominations, but studying one particular science, will be taught by the same professor or assistant professor, as their attainments will enable them, differing only in this—that one class of students will study to a certain extent, whereas the other class will finish the whole course of the science. For instance, students of the *Plant Culture* and *Medical* sections will study botany in the same class, but students of the former section will complete the botanical course, and students of the latter section will study this science only to that extent as is necessary for him to learn for *therapeutics* and *pharmacy*. The same might be said of chemistry, geology, veterinary, engineering, drawing, land surveying, &c., &c. The proposals I here advocate have *economy*, *efficiency*, and *absolute success* for their foundation; and since the science of plant culture is allied, other plans of tuition have been, are, and will continue to be failures, with heavy losses of money. The foregoing proposals will also, if carried out, be productive of the grandest result, in external appearances, the world over saw in the educational line. The proposals, as applied to India, do not in any way interfere in the University examinations and conferring of certificates and titles. In these respects the present University systems remain unaltered to the very letter.

Like the *New York Times* writer, I hold scientific and technical journals are necessary adjuncts to high class education of all denominations.

O. L. BRYCE.

Bahraich, Oudh, April 10, 1883.

NOTE.—We have been compelled to considerably curtail our correspondent's letter. What we have reproduced is the gist of his proposals. We rather fear, however, that a good many things will have come to pass before a University of the Allied Sciences will be considered a pressing need for India. —ED., I. A.

THE UTILIZATION OF SEWAGE.

TO THE EDITOR.

SIR,—In your issue of April 2nd, appears an article on "Utilization of Sewage," in which an undated analysis by Dr. Voelcker of sewage sludge is made use of to support the writer's opinions.

Those who have read the article alluded to should read further the evidence given by Dr. Voelcker on the 28th July 1881, before the Royal Commission on Agriculture in which the following information will be found:—

Q. 57,373.—Do you think that there is any mode of utilising sewage profitably?

A.—The application of sewage is a complicated question; it is a sanitary question, and an agricultural question. The sanitary question is the one which has first to be solved, which must be solved at all expense, and frequently at a loss as regards the application of the sewage.

Q. 57,374.—Do you still adhere to the opinion which is given in the article which you wrote on the influence of chemical discoveries on the progress of agriculture in the *Royal Agricultural Society's Journal* in the year 1878 in these words: "in my judgment the most economical plan to dispose of town sewage is to carry it, if possible, bodily far enough into the open sea to destroy any chance of its being brought back again by the tide?"

A.—Yes; and in confirmation of that, I would say that it is now the very scheme which is being adopted in the lower Thames valley. They carry it all the way down to the sea now.

Q. 57,375.—Does that opinion imply that the sewage cannot under any circumstances be economically used?

A.—Yes, the expense of the application is greater than the benefit derivable from sewage.

A. D. O.

Cawnpore, April 19.

NOTE.—We thank our correspondent for his note: the information is new to us. But the analysis by Voelcker, quoted, was not intended to show what was realised for the sludge, but merely to show its agricultural value. Being aware that nothing is obtained for it at Leicester and other places, we could not attempt to prove that its application would be profitable at any given place, and therefore warned the Municipality of Calcutta not to look for profit until the public safety had been first considered. Everything being favourable, the cost of its application would not be equal in all places, consequently the benefit derivable might not in many cases cover the cost. There are instances, however, where profit has been the result, notably of land near Edinburgh, where the rental increased from £3 to £30 and £40 and over £50 per acre.—ED., I. A.

HORTICULTURAL SOCIETIES.

TO THE EDITOR.

SIR,—In the last issue of your paper, you publish a complaint made by the President of the Calcutta Horticultural Society regarding the difficulty of obtaining new members. The same issue contains a summary of the work done by the Madras Horticultural Society, and in that, a similar complaint is referred to. It may be the case that these societies find a difficulty in filling up their lists of members under the altered conditions under which we now live in India, but if it is so, the reason is not far to seek—the societies are not organised on a popular basis. It would be a great pity if either society were to come to grief, for they have both done good work in their day; but it is idle for the presidents to stand and wring their hands because the number of their members is falling off. The main reason why the number of members in either society is so small is, I apprehend, because the rates of subscription are fixed at a figure far too high to admit of any large number of people joining. I believe that if the subscription were not more than Rs. 12—better, Rs. 6—per annum, each society could have a very large list of members, who would pay this sum to enable them not to get, as they would under the present rules, supplies of seeds, &c., gratis, but to purchase at low rates, which would recoup the society, plants, seeds, &c., just as they required them. The smaller subscription would support the societies in their good works, and they would become co-operative societies for the objects referred to.

It is so easy now-a-days to get out supplies of garden seeds from England or Australia, that unless there be a pecuniary advantage in doing so, people will not join the society in order to obtain the plants, &c., distributed by it. Public spirit exists, but it is few who can afford to exercise it at the rate of these societies' subscription. Another thing is that these societies have got to be looked upon as close institutions, the management being in, and continuing in; the hands of the same people for years together; and it is not likely, unless some degree of the popular element is admitted into their constitution and management, that they will attract members. Until they take up generally, and urge on Government strenuously, the duty, necessity, and advisability of endeavouring to promote agricultural reform, it also seems a farce for them to include the term "Agricultural" amongst their titles. At present, as far as the outward world is concerned, it is difficult to see how they merit the title.

A few years ago, I wished to join either one or both of the societies above referred to, but the rates of subscription (giving me privileges I did not want) frightened me off, and I am still—

NOT A MEMBER.

COTTON SEED.

TO THE EDITOR.

SIR,—I would feel very highly obliged if you could furnish me information as where to obtain the seed of a kind of cotton which I remember to have read something to the following effect:—

"Its cotton is extremely soft; the plant attains its full growth in 3 or 4 years, and lives for several years after that."

Should you favour me with the name of some other superior soft cotton, if I mis-remember the above particulars, and where to obtain its seed.

ISHAR PARSHAD PUNDIT,
Head Teacher, Hindoo School.

Lahore, March 20, 1883.

The Indian Agriculturist.

CALCUTTA, MAY 1, 1883.

PLANT DISEASES.

(HEMILEIA.)

THIS is the familiar denomination of a fungoid pest (*hemileia vastatrix*) which, for the last ten or fourteen years, has mocked the efforts of coffee-planters, and the ingenuity of certain specialists. It exists to-day—a living proof of past and present neglect of the simplest laws of vegetable hygiene.

Appearing first in the remote district of Madulsinna, in Ceylon, on young coffee planted in forest soil, no suspicion was entertained that its origin was due to starvation, or defective treatment. It indeed was for a time a puzzle even to such eminent mycologists as Berkeley, Broome, Cooke, Thwaites, and others; so much so that it could not be said to belong to any known class of fungi, although it was considered to be intermediate between ordinary mould and *urelos*. Since its identification, specialists have had to deal with the most varied and complicated aspects of phenomena, processes, and influences, while endeavouring to establish its characteristics, and yet, even after the lucid investigations of Mr. Marshall Ward in this direction, we are far from having attained proofs of its origin, or having sensibly retarded its progress. The pest still rages, and men who were rich are poor. Enough has been said and written on the life-history of the fungus: to this therefore we will not advert; we will further endeavour to steer clear of the atmosphere of theory with which this disease is so peculiarly surrounded, and proceed in a calm manner to consider why, after a ten-years' siege, so little has been accomplished towards its annihilation. Starting from the fact that the disease first made its appearance amongst young coffee, growing in virgin soil, we might on this account banish at once from our minds the idea of its being due to any defect in the soil itself, and would be supported in this by the knowledge that the disease was not confined to plants growing in soil which, from age, appearance, and out-turn, might have been classed as poor; but that, on the contrary, it raged amongst plants of the most apparently healthy type. We say *apparently*, because it is from this point that we will endeavour to show how planters have erred. It has been long agreed that the disease is a fungus; well, the question occurs, of what nature is the soil in which fungoid growths delight? Manifestly it is fermentative, and may be either hyper-organised animal matter or vegetable matter in a like state. In such matter, fungi may originate; in the presence of it, we know they fructify. These diseases, in short, may be due to decompositions as numerous and peculiar as are varieties of the order, and may be brought about by what is intended to be kind, but what we will endeavour to show, is really bad treatment. It is not our intention to enter into the mycological details of the pest in question: it is enough for us that it is fungus; we, therefore, must start from beyond the margin of circumstances which proclaimed its advent, and consider whether at or before this period, our mode of treatment was such as might have given rise to it. We will accept it then as a broad axiom that fungi luxuriate where decomposition prevails; that wherever this species of growth is seen, it ought to excite suspicion, for it is as much an indication of some internal disturbance, as are the appearances of scarlatina and small-pox. Coffee then, being infested by a fungus formerly unknown, points to the conclusion that by some means or other we have disturbed the conditions essential to healthy growth. It has been shown that this disturbance is not the effect of starvation; it is therefore very possible that it is the result of error. Were we ourselves to feed solely upon grass, we would be poor subjects.

Mr. Marshall Ward has discovered and demonstrated the laws of the operation of the disease. Beyond this he has not gone. We consider that to successfully contend against it, we

must discover its origin. Practical planters have tried topical treatment of the most varied description, with the object of killing it: prominently the process of Storck, appropriated by Schrocky. The disease, however, is proof against all these, for no specialist has endeavoured to deal with the cause. They have, as it were, waged war against the fungus, without attempting to cut off its supports. Fungi, we have said, revel in decomposing or decomposable animal and vegetable matter. Is there anything in our present mode of culture that might induce this condition in coffee sap? That is, lead to a disturbance of the conditions of internal processes peculiar to this plant in a state of health? Has anything intervened or interfered with the circumstances under which, in days gone by, good crops were realised? Unhesitatingly, we say yes. Else the fungus, now so well known, but improperly considered, would not be new.

In animal life there are what might be considered two states of good health, viz., that in which adipose tissue predominates, and that characteristic of muscle. The former we know to be most susceptible to decay, and the latter least susceptible to disease. The inference that the same peculiarities may hold good in plant life is not merely speculative. Pamper a plant with nitrogenous and saccharine fertilizers, and we have an apparently luxuriant growth, but we produce a readily decomposable or fermentible sap, capable of giving birth to fungi, and on which fungi, if the conditions giving rise to it be not speedily checked, would rapidly fructify.

It is thought by some that the disease must, like typhoid or scarlatina, burn itself out. This cannot be, so long as we supply fuel, nor can the most powerful anti-septics, while such conditions exist, do more than destroy the growth. Be they ever so penetrating, they cannot destroy the conditions. We must therefore supplement these certainly effective antiseptic measures against propagation, by more radical measures towards complete suppression. That is, we must check germination, and remove the conditions essential to evolution. For so long as evolution is possible, suppression of the mere external growth is futile. Assuming, then, that the coffee plant of to-day is too rich in easily fermentible constituents, and that consequently the absorption of mineral matter essential to hardy growth, and on the presence of which the stability of the sap depends, has been interfered with, our duty will be to discover in what manner this has come about. We ourselves do not pretend to have discovered this; but like lookers-on at the game of chess, imagine that we have discovered a false move, the which, as the game seems likely to be indefinitely prolonged, we would now point out. To be brief, we have, during the progress of the disease and for a considerable time before its advent, been fattening our plants instead of rendering them muscular, and so long as we continue this oleaginous treatment, we but fertilize the soil in which fungi revel, and from which, we repeat, even if we could simultaneously destroy all externally existing growth, fresh fungi would spring.

Most plants contain, in a more or less degree, certain unorganised ferments, the presence of which is proved by the diastatic action of their juices on starch; any excess therefore of organised matter, be it amylaceous, albuminoid, or mucilaginous, in the sap of plants, will call these peculiar ferments into play, and result in organised ferments, producing plagues such as have for years engaged the minds of workers in all departments of agriculture. That these rapidly multiply we know, and that they may blend and produce forms of a more virulent type is probable. Without therefore saying one word to detract from the value of external remedies, which at best are but powerful auxiliaries to fundamental measures, we will proceed to show how, under the present system of culture, diseased conditions may exist. To do this we must consider the question in retrospect, and ask ourselves, if, in the beginning, we neglected any ordinary hygienic precautions which may have given origin to the scourge. Everything points to such an omission. Want of railways forced planters to fall back on such fertilizers as were near at hand; of what did these consist? We speak from direct knowledge when we say that such fertilizers consisted mainly of the very elements which would lead to a fattening of the sap, a condition which could not, considering the robust nature of the plant, be achieved all at once,

but like anæmia in man, be a matter of slow process. The fertilisers, then principally used were coffee pulp, a readily fermentible substance rich in nitrogenous matter, gum, &c., but poor in mineral matter; cocoanut cake, a substance more highly nitrogenous, containing sugar and gum, but still poorer in mineral matter, and castor cake, even more highly nitrogenous, and poor in mineral matter: these with ordinary field and stable composts were the agents *then*, and we think now, much in vogue. They were, we know, long before the advent of the disease, and for a long time afterwards, lavishly applied. It is true that some planters more enlightend and more persevering than others, did at intervals apply bone-dust, and like substances, but these men were few in number, and it is questionable whether, in the presence of an excess of organic matter, absorption of the essentials applied could have gone on to any appreciable extent. Given, then, these circumstances preceding and following the disease, we have not far to seek for its origin. That the disease has not succumbed to topical remedies calls for no surprise. The Germans, with all their power and *clat* of victory, could not reduce Metz; the French succumbed to that power which no life can withstand—starvation. So must hemileia. And surely as the conditions which gave origin to it remain, as surely will it continue to grow. No matter how much of the fully developed fungi we may kill, we are not one step forward: our attention must therefore be directed to cutting off its supports. This we say after a matured practical study of the disease, and subsequent consideration of the numerous views regarding it, expressed in that eminently practical organ, the *Ceylon Observer*. We have looked on for many years, hesitating to add to conflicting current opinion, but as the disease affects us in South India, we can no longer keep in reserve our privilege to speak. We repeat, then, that it appears clear to us that if we are ever to succeed in mastering the plague, we must give our best attention to fundamentals, and that our first duty in this direction will be to destroy the conditions essential to its development, the first step towards which will be the abandonment of the use of the highly nitrogenised fertilisers mentioned. Next, we must endeavour to discover by examination of plants which have not been affected, that is, plants grown where the disease is as yet unknown, the characteristics of truly healthy sap, to get, in fact, at its exact constituents, so that we may compare it with that peculiar to diseased conditions, and so be able to judge when we have brought it to a healthy state; and when at any future time like indications of disease occur, we may know in what way we have deviated from necessary conditions. Judging from the agreement in certain essential effects, brought about by the combined action of auxiliary remedies, such as carbolic acid, sulphur, &c., with tonic treatment, we are sanguine that the same treatment, *after we have completely withdrawn the evil influences mentioned*, would, if universally adopted, free us from the pest. But we emphatically say that even should we discover a specific, which would penetrate into every fibre of the plant, and so destroy every spore, the disease, unless we are prepared to use the remedy in perpetuity, would reappear with as great virulence as ever. We must adopt measures to prevent further growth, and this we can only do by withdrawing the essentials to growth, and withholding the same for a considerable time from the soil. In the *Journal of the Agricultural and Horticultural Society of India* (Vol. VII, Part I) there is a reprint of an excellent paper by Mr. Carruthers, F.R.S., in which it is fairly demonstrated that wheat mildew and rust are one and the same fungus in different stages of development, and that a still earlier stage exists in the shape of the *acidium* on the leaf of the barberry. From this it might be reasonably inferred that hemileia, phylloxera, and such like pests are also higher forms of other fungi. Bearing in mind the relationship of hemileia to common mould, we would to a certain extent be inclined to favour this view, especially knowing as we do that the forests in the vicinity of Madulima, where hemileia was first seen, abound at certain seasons in low forms of vegetation. But, we argue, such were not new, and that had the coffee first affected not offered a ready nidus by reason of its diseased condition for the spores of these lower forms of fungi, granting it to have originated in this way, we should never have heard of the disease. If it is contended that the

coffee at this time was perfectly sound, we would ask why the spores of the lower fungi, such as from which it may have sprung, did not in earlier times find on it a congenial soil. It might be here answered that the primary form had only at this time sprung from something else, that it was the result of the blending of several heretofore known fungi under peculiar conditions, in the humid depths of the forest, and that when the dry season came round, the spores of this new creation were projected into the atmosphere, and chose as their habitat, coffee. We say again, however, that had the sap of the plants at this time been healthy, no form of lower vegetable life could have germinated therein. Whether or not, however, the disease had its origin in this way, or whether of primordial growth when first seen, is a matter of little consequence, for the remedy would in either case be the same. Mr. Carruthers, concluding his remarks on the wheat pest, says:—"From the history of the fungus, it is manifest that at no stage is it under our control, and though we can take steps which may prevent at different stages the unnecessary increase of the spores, we must be baffled in any attempt to prevent the appearance of the disease, whether in the rust or mildew stage. We take objection to this conclusion, because we do not believe that fungi can come into existence, or thrive elsewhere than in unhealthy places; their habitat is the morass and the swamp, the interior of forests, badly drained fields, sewers, cesspools, and places where the full influence of the sun and the atmosphere is not felt. They are as surely the result of a bad state of things, agriculturally, as are typhoid and malaria, from a sanitary point of view, and presumably like those latter may, if we go the right way about it, be stamped out. It is to be regretted that Governments have neglected to apply the resources for the discovery of causes and the means of removing them, which the knowledge of our time renders possible. Contented with various curious discoveries, they do not seem to realise that certain changes and deteriorations in important staples are, bad though they be, but indications of greater mischief. Does the study of coffee disease lie outside the duties of Agricultural Departments?"

THE IMPROVEMENT OF INDIAN AGRICULTURE.

LAST year, amidst a great flourish of trumpets, Mr. Buck published a resolution of the Supreme Government on the organisation of Agricultural Departments in the various provinces. It contained a number of statements which no one could dispute, and pointed out how it is incumbent on the State to do all it can in India to promote progress in agricultural matters; it also contained many statements, such as that, for instance, regarding the necessity of deferring action until more information has been collected regarding the condition of the country and the people, which are not only incorrect, but very misleading. Half-a-century and more of rule has put the Government of this country in the possession of sufficient facts, *if only they would read them rightly*, to guide its action in promoting agricultural reform. There is also the experience of the methods adopted in all parts of the civilized world from Great Britain to Japan, to show them how to proceed. However, our rulers have preferred to proceed in a slow manner, and it will be useful to see what is being done.

The main idea evolved in Mr. Buck's resolution was the combination of the work of revenue settlement and agricultural improvement in one department. This of course is a most ill-advised course, because it will cause all the efforts for improvement which may be made, to be looked upon by the ryots as so many endeavours to find excuses for increasing the land rent. Very little experience is necessary to make any one aware of the fact that the ryots look with suspicion on all efforts promoted by their landlord (the State) to bring about an increased rate of production from the soil, no matter how truly disinterested the views of the Government may really be. What, then, will be the ideas of the ryots when they see the self-same officers, who are engaged in fixing the rent, doing all they can to induce them to improve their systems of husbandry, and thereby give an excuse—as the ryot will believe—for increasing that rent? The idea has, however, been accepted by most of the local Governments, and is being carried out, but

very little else has been or is being done. It will be well to see what is being done in the two provinces where agricultural improvement has hitherto received most attention—viz., Madras and the N.-W. Provinces. The former province has for many years now had in its service a specially trained agricultural expert, and under him has maintained an experimental farm in which many useful investigations have been carried out; it has also for the past six or seven years been supporting an Agricultural College, which has been doing good work under considerable disadvantages. This work as begun to show signs that it is having effect in the southern presidency, as we have recently heard of native gentlemen, owners of large property, taking to agricultural pursuits, adopting improved implements of husbandry, and employing the trained men turned out by the Madras College as their managers. We cannot think, however, that nearly as much has been, or is being, done in Madras as the means at the disposal of the local Government would admit of. It is very probable that Mr. Robertson has been crippled in his efforts by want of support from his superiors, or we find frequently in his reports references to schemes or extending his work, but in after years no further reference to them. It is a great pity that the Madras Government do not see their way to extend the work of its agricultural officers, of which they now have two highly trained and of considerable experience in India, and they must, amongst the men who have been educated in their Agricultural College, have abundant material for widely extended operations. Mr. Robertson was not long since appointed Agricultural Reporter to his Government, whatever that may mean, and it was then stated that he was to report on the whole of the Madras Presidency with a view to devising means for dealing with it agriculturally so as to avert famine. No doubt the work could not be put into better hands, but now one man was to be able to perform it in the ordinary course of an official life in this country does not seem to have struck the person who proposed it: it is in fact impossible; and made the more so as Mr. Robertson was to carry out the duty in addition to all those he has heretofore performed, and which for eight or nine months in the year tie him to his headquarters at the Agricultural College.

At the same time that the extension of Mr. Robertson's duties was made, the Madras Government appointed its Director of Revenue Settlements to be Director of Agriculture. What the value of this step may be it is difficult to surmise. We have already indicated the evils likely to result therefrom. The able officer who is appointed to fill this post is probably, like his companions in the Revenue Department, as innocent of agricultural knowledge as a new-born babe, and there are signs of his already having "put his foot in it," if we are to believe the Madras papers; whilst we also see that not long ago the Madras Board of Revenue wanted Mr. Benson, when acting for his superior during an absence on furlough, to revert to the old exploded idea of endeavouring to teach the adult ryots by means of a commercial farm conducted by Government. This last idea shows that although in many ways the epithet "benighted" is inapplicable to Madras, in things agricultural it is benighted enough and we fear that the newly appointed Director of Agriculture may, like so many others who have not studied the subject thoroughly, be led away by plausible arguments, and force on his department an incubus which we are glad Mr. Buck had the clear-sightedness to relieve the operations of this N.-W. Agricultural Department from, whilst he was directing them. Besides its direct agricultural operations, to which we have referred, the Madras Government are forming a strong veterinary department, which will combat and endeavour to suppress cattle-disease. These operations cannot fail to do great good to the country, but until our live stocks are better fed and cared for, tremendous losses must frequently take place amongst them.

Turning now to the N.-W. P., the only other province which has as yet made any real profession of work in this line, what do we find?—A department called that of Agriculture and Commerce, and devoted almost entirely to the collection of statistics and the supervision of land revenue subordinates.

If the latter duty were carried out by such trained agents as a landlord in Europe would almost solely employ, the department would, or might, be fulfilling a great work. Besides this, the department has an Engineer officer endeavouring to find a way to cure the ills caused by the mistakes of ignorance of former engineers, viz., the effect of *red*. Again, there is the Cawnpore farm on which Mr. Fuller has been doing as good work as could be expected on so badly selected a site, but jumping to conclusions on altogether insufficient data as was also to be expected from an amateur. Experts are liable enough to this mistake, but when amateurs are taken with an idea, it usually carries them away. "Nitrogen" is no doubt an element which is very easily exhausted, but to make it a password on the strength of a few isolated experiments is a gross blunder. On this farm, we were led by the last report of the Director to believe that a college, something similar to that at Madras, was going to be started. The idea was under discussion in December 1881, and the Director stated that Mr. S. Hill was to be the Principal of the College; that gentleman is now going home, so we must believe that the plan has broken down, whether from differences of opinion between Mr. Buck and the local lights, or from an ill-advised refusal of sanction from the Secretary of State, it does not matter much, as, whatever the cause, the occurrence is most lamentable, and coming just as the department was apparently taking a new departure in a right direction, will be regretted by all who have the interests of Indian agriculture at heart.

In the other provinces of the Empire, very little has yet been done. In Bombay there is an agricultural class in connection with the College of Science at Poona, but it is not doing much, nor can it be expected to, unless placed on a firm and efficient footing. Perhaps Mr. Ozanne will be able to do something when he returns to India after his study at Cirencester. In the Central Provinces, Mr. Fuller is doubtless infusing his energy into the operations of the local authorities, and we only hope that he will be able to do something satisfactory with the Nagpore farm. In Bengal, the Lieutenant-Governor goes on throwing away large sums of money in sending young men to Cirencester, who, on their return crammed with book knowledge (for we are credibly informed that at Cirencester the Bengal students are of no use outside the College) will have to spend two or three years in learning how to apply what they have learnt in England to Indian conditions before they will be of any use. The money spent on these scholarships (something like £900 a year) would educate about 40 or 50 students at the Madras College, where the students, in addition to obtaining a very similar theoretical knowledge to that gained at Cirencester, would have seen it applied to Indian conditions, and so have been, at the end of their studies, much better fitted for immediate service. What the Bengal Government is going to do with its students when they return from England, as two shortly will, has not yet been announced. In Burmah, Assam, and the Punjab, officers have been appointed in accordance with Mr. Buck's resolution, but it does not seem that they know very well what their duties are or may be. In fact, the whole question of the organisation and duties of these new Agricultural Departments requires overhauling, and the details worked out by specially qualified persons. It is very easy to sketch out a general scheme for anything, but we hope that the local officers appointed under Mr. Buck will be able to work out thoroughly practical methods for attaining ends which it professes to have in view—the improvement of Indian agriculture.

THE BENGAL AGRICULTURAL SCHOLARSHIPS.

IN a separate article, we have summarised briefly what is being done in India for agriculture by that resuscitated gemini of a department, the Revenue and Agriculture. We have stated our conviction that the combination of revenue and agricultural duties assumed by the department or rather the imposing of some of the work of the department on revenue officers, thus identifying in the minds of the peasantry the fixing and enhancing of the revenue, with almost everything

emanating from the agricultural bureau—in short, the rolling of two single men's duties into one, is likely to produce distrust, and veiled opposition, among the ryots to every single improvement proposed by the agricultural authorities; and instead of furthering agriculture, materially retarding it. We hold that until officers properly qualified to deal with the intricate problem of Indian agriculture, not merely jacks-of-all-trades who can be pitchforked into all sorts of square and round holes, are officering the department from its highest to its lowest grades, not only will a steady, determined resistance to the plans, suggestions, schemes, &c., of the Agricultural Department be raised up among the peasantry, all the more steady and determined, because seemingly acquiescent, but well-meaning-clever men, full of theory, and, it may be, crammed with the latest and most advanced text books and scientific treatises, will work mischief almost irreparable, and air their fads in resolutions and reports, and before a wondering peasantry, who will listen, look on, and if they do not laugh at the *sabab* when his back is turned, will wonder what it all means. The very substantial agricultural scholarships instituted during the time when Sir Ashley Eden ruled Bengal, and since then further developed, are, we venture to affirm, better fitted for a people centuries in advance of the average Indian peasantry. What connection there is between mere power of cramming the contents of books for the purpose of disgorging them at examinations, and an intelligent study and practical acquaintance with the various operations implied in rural life in India, is probably known best to the well-meaning men who planned the Bengal Agricultural scholarships. We venture the opinion that there is scarcely a student at Cirencester College who at a pinch could not perform every single manual operation necessary on an English farm—from cleaning a byre to buying or selling a pig at a market; who could not plough and trench, sow, groom, milk, &c., with more or less skill. To place men of this stamp in the same category with the contemptible men of books and examinations sent to Cirencester from Bengal, men who never twisted the tail of bullock, or carried a plough on their shoulders unless by proxy, is to insult the former, and to expect from the closet student the knowledge of the practical man of the world. We do not by any means undervalue intellectual training and knowledge derived from books, but we hold that the qualities most imperatively desirable in all who aspire to become the leaders and teachers of agriculture in India, are the power of accurate observation and of exhaustive experiment, based on a practical acquaintance with the whole details of agricultural and rural life in India. To confer such rich scholarships as those of Bengal on clever book-men, distinguished university students who have shown no aptitude for, or knowledge of, the work of an ordinary ryot, who probably could not distinguish one crop from another if asked to point out one or other as they stood in the field, and whose ignorance of things agricultural is contemptibly conspicuous, is, to say the least of it, astounding. We are prepared to hold that of all places in the world least suitable for the teaching of Indian students of agriculture, Cirencester is the worst. The class of students mainly found at Cirencester are composed of the sons of wealthy farmers, land-owners, and it may be younger sons of the nobility, a fair proportion of whom, as in most educational establishments, attended by the sons of the wealthier classes in England, are, to say the least of it, not absorbingly devoted to study. Luxury, leisure, and lectures are not the best preparation for the study of Indian agriculture. Indeed, it seems to us a gross waste of public money to send these clever Indian young men to Cirencester, to acquire a more or less thin English veneer, a parrot-like knowledge of crops, rotation, soluble phosphate, manuring, farm machinery, and costly English and Continental methods of working and winning crops in order to return to India, and impress these and such-like theoretical teachings on Indian ryots, whose whole household, farm animals, and labourers could live for a week on what it cost the Bengal agricultural scholar for a game at billiards in England. We ask the Government of Bengal what it expects from these Cirencester scholars, who are now being steadily manufactured at public expense? What have any of them done for agriculture, or what does the Government expect them

to do for agriculture when their scholarships are ended? Will it provide them, highly paid, posts in the harmonious general department of Revenue and Agriculture, and leave them for the rest of their official existence to do revenue work, and write smart essays by way of reports and returns? If this is so, then there are hundreds of young men in India who could be trained to that sort of thing at considerably less expense. On many occasions in the pages of this journal, we have ventured to counsel the Imperial and Local Governments on matters agricultural; but it is probably no part of the duties of a public journal to teach Indian departments their work, and show them how to effect it best. It does, however, seem to us that there is a gross and unjustifiable waste of public money in founding such rich scholarships as those of Bengal, when, in the whole province, there is scarcely a pice spent in any legitimate effort to teach the peasantry, or inoculate proprietary ryots with ideas on agriculture other than those which they and their fathers have followed with unvarying routine for ages. This mere playing at agriculture is wasteful and disgraceful, and the sooner it is ended the better.

THE YELLOW PAMPHLET.

THE yellow pamphlet, "Indian Wheat versus American Protection," has been much honoured. It has been noticed in the budget, and has recently formed the text of a letter from the Bengal Chamber of Commerce to Government. And it contains some very useful statistics. It is, however, disfigured by some highly seasoned criticisms of a not very profound sort, and is more destructive than constructive in its tendencies. Nor is it always accurate. And this last is a serious defect.

At page 20, we find—"The lowest rates ever sanctioned for the carriage of grain by rail are on the Punjab Railway, viz. (1-7th pie per maund per mile) 0-748 shillings per quarter per 100 miles, . . . and are considered to be so probably unremunerative that the present nerveless management of the lines have never given the public the advantage of them. But all the same, we must not withhold our admiration for the enterprising and far-sighted policy of the Board of Directors of the Sind, Punjab, and Delhi Railway, &c., &c." This is eloquent enough. But it is unfortunately not in accordance with facts. At certain seasons of the year, the rate mentioned, 1-7th pie, exists, and the public has advantage of it on both the East Indian and Oudh and Rohilkund Railways. *Videri quæ esse* has, for so many years, been the policy of the Punjab, that it is not surprising that others act while the Punjab only legislates. The point is, however, whether 1-7th pie, which is equivalent to one-half-penny a ton per mile, is not too high. That lower rates than are at present quoted could be given to the public seems to be undoubted from the following consideration. Official returns show that on the East Indian Railway the average cost of moving one ton one mile is pies 2-34, and the average profit pies 4-09. In other words, there is a profit of about 200 per cent, which leaves a large margin for a reduction of the average rate on the railway. If railway managers could only be brought to understand that a low rate and a wide public is the most profitable form of business in railways as in other transactions, what a revolution in things there would be, and how rapidly the public which pays the railways would increase in area.

We are entirely with the author of the pamphlet in his main object—the reduction of rates. But we doubt if he is right in his denunciation of extravagance on Indian lines. We believe that they are generally managed economically. We have never seen a comparison made with American railways; but one with English railways was in favour of the Indian concerns. However this may be, the economies which could be enforced would probably not be very great, and, with profits of 200 per cent on cost of carriage, do not require to be made on the East Indian, at least before the experiment of lower rates could be introduced. On other lines, particularly on the Punjab line, the margin is smaller. But there ought to be little alarm in making the experiment anywhere, for all experience in all business is in favour of low profits and large sales.

One of the most remarkable facts mentioned is in the last appendix of the book, namely that Government, in the face of the fact mentioned above, that 1-7th pie is a rate in operation on two railways in India—a fact which ought to be known to authority—has, in its contracts with the South Mahratta and Central Bengal Railway, limited its power to reduce rates below 3th and 4th pie respectively. We wonder who the advisers of Government were in this matter. If private enterprise cannot be encouraged without mischievous reaction of this sort, it is a question whether it should not be abandoned in favour of some other policy.

The first object of the writer of the pamphlet is the reduction of rates, this has our entire sympathy. So has the second object—the more rapid extension of the railway system. This our author would achieve by capitalising the sum now yearly spent on productive works, and spending it at once. Thus, taking the annual sum at two millions, he would spend the equivalent capital of 50 millions in building 20,000 miles of railway in 7 years. This question of capitalisation is not new. It was, we believe, submitted to the Secretary of State, and vetoed. But, supposing that it should be permitted, we think the author of the yellow pamphlet is going rather too fast. The sudden construction of 20,000 miles of railway would seriously derange the produce and labour market, raising materially both the cost of work on the line and the price of iron placed in it. About 12 years ago, as is well known, the very rapid extension of railways in America had this effect—making the fortunes of English iron and coal masters, and vastly increasing the cost of both minerals, to the injury of railways both working and under construction. Perhaps, however, the writer is speaking hyperbolically; and that some more rapid rate of progress is needed, we readily admit. And not only is it desirable in Indian agricultural, but in Indian manufacturing, interests also. If it were certain that railways would be rapidly extended, it would pay capitalists to set up in India iron-works on a scale of sufficient magnitude to make such concerns profitable. Could not the Secretary of State be induced to permit partial capitalisation of the two millions? If, for instance, so much of it were capitalised as to produce 10 instead of 50 millions, a great deal might be done which is now impossible.

The author of the pamphlet is hard upon Government as financiers, but he surely falls into a fallacy himself. In discussing capitalisation he says—"And as to increasing the amount of sterling debt, that *bête noir* of the Indian financier, nothing would be easier than to arrange that the guarantee was to be given to the company, not on the amount of sterling lodged in the treasury at home, but on the amount of rupees lodged in the treasuries in India. This simple arrangement would turn the whole into a 'rupee loan.' Quite true; but what is the advantage of a rupee loan? The *bête noir* of the Indian financier in respect of sterling debt is not the sterling, but the loss on exchange. But how does a rupee loan remove this loss? It of course cannot do so unless the holders of stock are in India, and spend the dividend here. But the experience of railway undertakings is against this. The shareholders are all English, with an exception too insignificant to be of consequence. The result is that the dividend, even when paid in India, is remitted to England; there is, consequently, competition for gold, and the silver is depreciated. It is true that while the stock is being paid up, the contrary operation takes place. For then there is a competition for silver, and it is appreciated. But this is merely a temporary alleviation. We do not think, therefore, that the author of the pamphlet has here given financiers any useful suggestion.

What he says about guarantees is more to the point. As it is now undoubted that all Indian railways, taken together, on the whole, pay a guarantee is no extravagance; but on the contrary, if it tends to attract capital not otherwise obtainable, it is extremely useful. And, if private enterprise is to have the oyster, and Government only the shells, the average returns may be reduced, and guarantees of a nature to attract capitalists become impossible. That private enterprise may, therefore, be injurious to the country, if the profitable lines are lightly made away with, is quite possible.

The author is particularly hard on the body-guard at Madras, which idles for eight and works for four months.

We suppose he must know something of the Viceroy's body-guard and its work: why should Madras alone be mentioned? The truth is, that so long as there are Viceroy and Governors, these things must and ought to be, especially in the East. The remarks about useless buildings seem to us to be too sweeping, though, to particularise, we may say that the defacement of Writers' Buildings seems to us a wanton extravagance, especially as all the interior arrangements of the building are less convenient than formerly. The author also must live in very high places, if his chuprasses get Rs. 84 a year. Usually they receive Rs. 60—not a very brilliant stipend.

He complains that one million is spent upon unproductive military expenditure. But how is this to be avoided? So long as there must be an army, there must be buildings. The army, though unproductive itself, makes possible useful production on the part of others, and is, in the present state of the world, we fear, a necessity.

The author is apparently a strong advocate for uniformity of gauge. This fighting for one standard has always seemed to us a mistake in India. It may have been an error to construct the Rajpootana line on the metre gauge. It would have been a far greater error to construct the Muttra-Matras railway on a gauge of 5 feet 6 inches.

In his contrast of America and India, he leaves out of sight the fact that Americans are willing to invest in the railways of America, but that Indians are not prepared to invest in Indian railways.

Mr. Grant White, who, as an American, may be supposed not to be prejudiced against his country, considers that English railways, in the matter of passenger-travelling at all events, are to be preferred to American. Nor are American railways always managed for the shareholders and the public, but for speculative rings—so that the policy employed cannot always be safely appealed to. "The public," said Vanderbilt lately, in reply to a remonstrance against some policy of his, "the public be damned."

THE JUTE INDUSTRY.

TO those people who are under the impression that the present exceptionally good times in the jute manufacturing industry here are likely to be permanent, a word of warning at this moment may not be altogether inopportune. At the outset, we would remind our readers that there is another place besides Calcutta where jute manufactures thrive long before many of our Bengal mills were in existence—an ancient town full of wealthy and enterprising traders, who are not likely to let the business slip, though their fingers, without making a strong effort to retain it—we allude to Dundee. Dundee, as most of our readers are doubtless aware, has been the seat of the jute manufacturing industry from the commencement: it has the finest jute mills in existence, and the experience of the most capable and practical men in the trade. For some years past, until very recently, competition between Dundee and Calcutta was very keen, and though Calcutta has wrested many a market from its older rival, the competition was very close, and many a company here had almost bitten the dust, ere the game was scored for Calcutta. But though Calcutta has the advantage in many respects of Dundee, that advantage is, in our opinion, only felt when profits are at a minimum; and when, as in the past year, mills are earning 30 per cent and more, we expect that Dundee can fully hold her own.

Advices from Dundee intimate that a change has come over the state of the jute trade during the past few months, shown not only by the full employment and increased wages given to the working classes, but also by the re-opening and extension of mills and factories in Dundee and its neighbourhood. The production, it is said, has been very materially increased of late, and will shortly be still further extended. During the latter months of 1882, several mills were re-opened, the most important being the Hillbank Spinning Company, the Grove Mill, the Logic Works, and the Westfield Mills, besides many important additions being made by the firms. The *Dundee Advertiser* in a recent article says:—"There is plenty of evidence that the production is being materially increased in other directions. Looms are being quietly added here and there, and looms which have been some time standing are now, or will soon

be, going again. In Forfar jute cloth is becoming a most important part of the production, and the number of looms employed at the five grades of hessians, mostly mangled, is now very large. How far this increased production is justified remains to be seen. After so long a period of dulness producers seem anxious to anticipate good trade, and are evidently to be well prepared for it. Up till now they certainly have not reaped much of the benefit, for few have yet got their dear purchases worked up, and it is the cheapness of jute which forms the encouraging element of safety to spinners and manufacturers at present. The demand, especially for yarns, continues very good, but whether Dundee can increase its export both of yarns and cloth sufficiently to meet a further important increase in production is questionable. The trade is undoubtedly large, but it is no longer confined to Dundee, neither is the extension of works by any means confined to Dundee,—the very large increase in Calcutta should be kept steadily in view,—and it does seem as if the production were keeping pace with the increase in consumption, if not more. While pleased to see such signs of returning prosperity manifesting themselves, it is well to remember that its duration may be made shorter by an excessive production."

In Calcutta extensions are going on by leaps and bounds; the Hooghly Mills with 300 looms are in course of erection, so are an additional 200 looms to the Howrah Mills; the Kankipara Mills with 300 looms are also under construction, so is a mill of 500 looms for the Samnuggur Company. The Goosery Jute Mills are about to put in another 74 looms, and we suppose that the addition to the Budge-Budge Mill will be not less than 180 looms. Messrs. Macneill and Co. are reported to be putting up a mill, and we observe that the Victoria Jute Company, Limited, has been floated in Dundee, with a capital of £200,000, for the purpose of erecting a jute manufacturing work in the neighbourhood of Calcutta, and carrying on the business in connection therewith, the Board of Direction consisting of well known Dundee gentlemen of long practical experience in the trade. Under these circumstances it would be as well if investors carefully reviewed the situation. At the present moment, consequent upon the very large profit made in 1882, jute mill stock is abnormally high. There is every probability that these large profits will be sustained during 1883, but with the close of this year we anticipate that things will return to their normal condition, if indeed there is not another crisis in the industry. It is absurd to suppose that the present high profits can be maintained; at the same time, the jute manufacturing industry is a perfectly honest and legitimate one; and if extensions are gradually introduced, and the manufacture is conducted with the necessary skill, care, and caution, a reasonable profit should always remain to be divided among the shareholders.

To show how the trade has developed, we quote the following from the *San Francisco Commercial Herald*:—"The annual consumption of bags and bagging for the Pacific slope has grown to such proportions as to overshadow most other descriptions of imported merchandise in value, and they are consequently becoming more a daily article of speculation and investment. A few years back, and between the months of September and April they were scarcely heard of, whilst now there is scarcely a day, certainly not a week, in any month, in which hundreds of thousands, sometimes millions, are not sold. As an illustration of this speculative action, a California-street house, that makes dealing in jute goods a speciality, on the 1st September last bought over five millions of Calcutta bags, and re-sold the whole in a few days at a small profit for delivery from January to June." These large speculative transactions are, however, often a source of danger, as a heavy failure demoralizes the market, as was the case a few months ago.

The exports of powerloom gunny bags to San Francisco, during the last four years, were as under: 1879—18,889,518; 1880—22,412,779; 1881—19,227,774; and 1882—16,495,380, while the shipments for January 1883 were no less than 7,620,900. It will be seen that there has been a steady falling off during the last few years, though the present year has opened well. We observe that the shipments to Australia are steadily on the increase, no less than 18,652,061 bags having been exported thence from here in 1882, as against 15,503,852 bags in 1881; 10,200,528 bags in 1880, and 10,605,942 bags in 1879. Australia and San Francisco are the two chief places to

which we export our bags, and it seems reasonable to suppose that we cannot undersell Dundee in ordinary times, and retain a profit of 20 per cent. We observe that, during the last few months, shipments of gunny bags have been made to the United Kingdom from here, which in our opinion shows that Dundee at present is full of business. During the present season, jute has ruled cheaper in London than it cost to lay it down, which is all in favor of Dundee.

MAJOR COUSSMAKER'S EXPERIMENTS.

MAJOR COUSSMAKER'S experiments in tussar sericulture in the Bombay presidency have not, it appears, met with the success anticipated. He is about to leave India, and in his last report, which has just been submitted, he says he cannot recommend Government to continue the experiments, as there seems little prospect of their proving remunerative. There are three causes which have led him to come to this conclusion. Wild silk, he says, is now exported very largely from China, and the price of tussar waste has therefore fallen to 1s. 3d. per lb. in England. The tussar cocoons of the presidency are also said to be smaller, and contain less silk than those found in other parts of India, while the expenses of collecting the cocoons or of rearing the worms in a state of semi-domestication is said to be great.

During the year 1882, Major Coussmaker's collection amounted to 25,031 cocoons, weighing 57½ lbs. Some cocoons which he sent home last year to Mr. Wardle to be sold, fetched 1s. 3d. per lb.; and the report of the buyers was "that the fibre from these cocoons is somewhat coarser than most tussar waste, and the cocoons have been opened; but this is not a serious drawback to its spinning qualities. China is now sending over such large quantities that the price of tussar waste is very low." In his attempts to increase the size of the cocoon by importing some of the large variety from Sumbulpore, Yamtasa, and other places, Major Coussmaker has not met with success. The moths, he says, have paired readily, and the worms have hatched out, but there has been no difference in the cocoons. This failure to improve the breed, Major Coussmaker attributes to the climate, and perhaps, he adds, the difference of food may be another cause. As far as quantity is concerned, it appears the result of rearing the tussar silk-worm in semi-domestication is most satisfactory. Major Coussmaker writes: "I have now been able to gather within six weeks three cocoons per running foot of hedge. My first worm, this last season, was hatched on the 9th May, and the first cocoon was gathered in 32 days' time. Of this particular batch of worms, I took careful notes; they numbered 380, and 347 of them spun cocoons, commencing on 7th June and ending on the 24th idem. They consumed 110 running feet of hedge, a few feet of which consisted of outtings that had been kept growing for a twelve-month, but the greater part of their existence was spent on a Lagerstromia hedge, which on the 1st May had been cut down to 2 feet in height, cleared of every twig and vestige of a leaf, irrigated every third day and enclosed within tarred screens of split bamboo, over which a coarse cotton covering had been stretched on rattan hoops; as fast as this hedge was eaten off, it sprouted again, and by the time the worms had reached the far end, the new shoots on the first tree were covered with leaves."

Major Coussmaker tells us that in his experiments he has only attempted the collection of tussar waste, but he considers it most probable that the production of perfect dry cocoons ready for the reeler, or reeled raw silk, may be more remunerative. Major Coussmaker puts on record in his report some valuable information regarding the bleaching of tussar silk, which has been placed at his disposal by Mr. Wardle. This gentleman, it appears, has made several experiments in overcoming the defects in tussar silk, and has proved successful in his attempts. Mr. Wardle's method, which will no doubt be of interest to those interested in the silk industry in this country, is as follows:—Mix in water, well impregnated with soft soap, carbonate of soda crystals, equal in weight to one-quarter of the silk to be bleached, and immersing the silk, boil it for a little more than half-an-hour. Then wash it

thoroughly first in hot, and afterwards in cold, water, until it is perfectly clean. Next, put it into a narrow deep vessel, and having added a few drops of ammonia to the liquid peroxide of hydrogen, so as to make it alkaline, pour it over the silk, until it completely covers it. The silk, while undergoing this treatment, must be kept perfectly in the dark, and if the peroxide does not remain alkaline, a little more ammonia must be added. Keep the silk in this state for 24 hours, then heat up the mixture till its temperature reaches 120°—130° Fahr., and let it remain at this heat for 12 hours, when it will be found that the silk has become bleached.

Although Major Coussmaker's connection with these experiments will now cease, we observe that the experiments are not to be entirely abandoned, as the plantations, &c., are to be transferred to the central jail at Yerroda, where it is probable they may be continued, as the authorities, according to Major Coussmaker, have always taken an interest in them.

COTTON IN THE PUNJAB.

THE year 1881-82 was on the whole a favorable one for cotton cultivation in the Punjab, and compared with the results of the two previous years, there is, during the period under report, a sensible increase in the area cultivated and in the outturn and value of the crop. The area under cotton and the outturn and value in 1881-82, compared with the results of 1879-80 and 1880-81, are as follows :—

| | Area in acres. | Outturn in cwts. | Value in Rs. |
|----------------|----------------|------------------|--------------|
| 1879-80 | 806,380 | 644,483 | 1,21,12,122 |
| 1880-81 | 781,729 | 653,917 | 1,31,08,069 |
| 1881-82 | 918,265 | 787,581 | 1,40,34,850 |

From the above figures, it will be seen that there has been an increase in area of 156,536 acres, and in outturn 133,664 cwts., and in the estimated value of Rs. 15,26,781. Though these estimates may have been capable of improvement, the Local Government considers that they may be taken as a fairly correct statement of the actual results of the year. The average outturn per acre for the province in 1881-82 was 96lbs. of cleaned cotton, or the same as for 1880-81. The district averages vary from 238lbs. in Jullundur to 28lbs. in Sirsa, where it is said that the crop was unusually poor owing to the heavy and unseasonable rain and the ravages of insects. The divisional average for the 10 cotton divisions vary from 58lbs. in the Rawul Pindee division to 149lbs. in the Umballa division. We observe that for some of the districts, the average outturn is placed very low, and in others very high, and it seems doubtful whether, in these instances, much reliance can be placed in the figures. The case of Kangra in the Jullundur division is specially noticed in the report. Here the estimated out-turn per acre is placed at 29lbs., and the Local Government is of opinion that this can be by no means a correct estimate for so favorable a year as that under report.

The cost of cotton cultivation per acre is given under the following heads :—

- (a) Lands irrigated and manured.
- (b) Lands irrigated but not manured.
- (c) Lands unirrigated but manured.
- (d) Lands unirrigated and unmanured.

Under (a) the cost varied from Rs. 11-11 in Goorgaon to Rs. 37-13-4 in Jullundur; under (b) from Rs. 6-12 in Goorgaon to Rs. 30-15-6 in Jullundur; under (c) from Rs. 6 in Goorgaon to Rs. 25-15-6 in Jullundur and Umballa; and under (d) from Rs. 5 in Goorgaon to Rs. 17-11-11 in Jullundur. Under all four heads, therefore, the cost of cultivation has been lowest in Goorgaon and highest in Jullundur. Here, again, we notice that the authorities are inclined to doubt the correctness of these figures, and the hope is expressed that the agricultural department of the province, recently established, may be able in future to assist district officers to improve statistics of this kind. The average retail and wholesale prices of cotton per cwt.

in the Punjab for the year 1881-82, compared with the year 1880-81, are given in the following table :—

| Retail price per cwt. | | Wholesale price per cwt. | |
|-----------------------|--------------------|--------------------------|--------------------|
| 1880-81. | 1881-82. | 1880-81. | 1881-82. |
| R. A. P. 21 7 3 | R. A. P. 19 7 5 | R. A. P. 21 12 1 | R. A. P. 18 7 6 |

The retail prices vary from Rs. 65-6 per cwt. in Jhelum to Rs. 28 per cwt. in Rawul Pindee, and the wholesale prices from Rs. 15-14-3 per cwt. in Rohtuk to Rs. 25-8 per cwt. in Peshawur.

The total amount of cotton imported during the year was 58,058 cwts., or 836 cwts. less than the imports of the previous year. In the total exports of the year, there is, however, a very satisfactory increase; the quantity exported amounted to 224,418 cwts., or 83,560 cwts. in excess of the exports of 1880-81. To this increase, Umballa, Jullundur, Goojranwala, Mooltan, and Lahore have chiefly contributed. Of the total exports of 224,418 cwts., Calcutta took 54,679 cwts., Bombay 15,089 cwts., North-Western Provinces 19,319 cwts., Sukkur and Kurrahee 40,385, Bikaner 3,600, and Afghanistan 4,896 cwts.

The total number of looms at work in the province during the year 1881-82 amounted to 136,733, as compared with 104,365 for the year previous, the increase chiefly occurring in the districts of Umballa, Rohtuk, Montgomery, Gujrat, and Hazara.

EDITORIAL NOTES.

WE have to acknowledge the receipt from Messrs. Robert Kettle and Co., Glasgow, of a very interesting series of tables containing the prices, from month to month, of the more important kinds of cotton yarns from January 1871 till December 1882—an eventful period of twelve years.

The most notable feature, it seems, in the prices of last year was the sudden and important rise in certain classes of yarns, owing to the war in Egypt, and the consequent diminution and deterioration of the cotton crop in that country. No doubt, these prices have since fallen to a point not much above the old rates, but it would be unwise to assume that all danger of another advance has passed away. On the contrary, when we consider that the poverty-stricken planters on the delta of the Nile are hurrying every bale into the market to raise money, and that April may witness the exhaustion of the crop, the long interval that must elapse before another can be grown may again afford a favourable opportunity to speculators to force up the price of Egyptian cotton.

ONE of the most remarkable events of the past year, connected with the Glasgow cotton trade, was the pitched battle fought between the Scotch Turkey red dyers and printers and the German alizarine makers. The Germans suddenly advanced the price of alizarine fifty per cent, and threatened, so it was understood, to stop supplies of alizarine, if the dyers did not give large orders at the new and exorbitant rate. Thus seized by the throat in a thoroughly Bismarckian style, our friends, the dyers, showed themselves to be quite equal to the emergency. They met the tactics of the Germans with the strategy of the hedgehog, and, by contracting themselves to half their usual bulk, they slipped cleverly out of the grasp of their Teutonic assailants. In other words, they cut down their consumption of cloth and yarn by something like 60,000lb. per day, reducing in proportion their demand for alizarine, and thereby gaining a decided victory over the manufacturers of that article.

About ten years ago the source of the Turkey red dye was either the madder root, or its product, garancine. Had any one at that time predicted that in a few years the garancine

trade would collapse, and the madder not be superseded by a chemical product, he would have been looked upon as unworthy of serious attention. Had the same prophet foretold that the waste products of gas-making, which gas directors were glad to pay the neighbouring farmer a good price for carting away and depositing on some moorland corner, would soon become one of the chief sources of revenue to the companies, his second prediction would have been looked upon by practical men as simply absurd and too good to be true. And yet both predictions have been amply fulfilled. Coal tar is now a great, and in some cases the chief, source of income to the Gas Companies, while its product, alizarine, is incomparably the most valuable and reliable raw material for Turkey red the dyers ever possessed.

Messrs. KETTLE in their circular say:—The past two or three years have not been very profitable for the great majority of producers in the cotton trade. Although the volume of business has been large enough to keep machinery going, it has not been sufficiently large to enable spinners and manufacturers to get fairly remunerative prices. The prohibitive tariff of the United States, the gradual increase of duties on imports in France, Germany, Austria, Russia, and Spain—are all so many deliberate attacks on our commerce and manufactures. A confederacy, composed of nearly all the civilised nations and of our own most important colonies, has been formed against us, and the Government of 200 millions of the largest consumers in the world are doing what they can to shut out the produce of our looms and spindles. The most important problem of the day is, How and where are we to secure compensation for this constant loss of business? How and where are we to find customers to take the places of those who are leaving us?

The first great field for the extension of our trade and commerce, says Messrs. Kettle & Co., undoubtedly is India. True, we have almost a monopoly of her trade, but that trade is capable of an expansion far beyond anything hitherto accomplished. In 1875-6 the total imports of merchandise into India amounted to 37 millions, while in the year 1880-81 these had increased to 50 millions, about seven-eighths of this sum being from the United Kingdom and her Colonies. But 50 millions sterling is only about 4s. 2d. per head of the population,—not quite a penny per head per week from our Indian fellow-subjects. The imports into the United Kingdom amount to fully £12 per head, and if the Indian people could only be brought up to a twentieth part of this rate, or to import a shilling's worth for every pound's worth imported here, the result would be that India would consume thrice as much as she does at present, and we all know that a trebled demand for the East means a flourishing trade for the mills and the factories, the dye-works and the print-works of Lanarkshire and Lancashire.

ROBERT KETTLE and Co., of Glasgow, in an interesting circular regarding the progress and prospects of the cotton trade, says:—

"Sir James Bain, who has devoted some time and attention to India, and whose opinion carries great weight, has arrived at the conclusion that, with India properly handled, we may safely defy Europe and America combined, and in spite of all their tariffs, successfully maintain and increase our mercantile and manufacturing supremacy. But Sir James goes further. He proposes to lead India into the great agricultural arena of the nations, there to compete for the highest prizes with all comers, and to wrest from the grasp of the American farmer the cereal championship of the world. Sir James calculates that if the present irrigation and railway facilities of India, which are inadequate and trifling compared with her dense population and boundless agricultural resources, were made abundant and ample, she could pay the freight from her own shores to Liverpool and thence to the sea-board cities of the States, where with her wheat, her Indian corn, and her millet, she could undersell the western farmer and realise a handsome profit for herself. Such a blow, vigorously dealt to the United States, up to the neck in protection, would be the grandest free-trade triumph of this generation. What an instructive spectacle it would be to see the American farmer imploring

Congress to protect him from the invasion of his Indian rival. Meanwhile India, taking her proper position as the greatest agricultural and food-producing country in the world, would become rich and prosperous, and ten times more valuable to us as a buyer of merchandise than ever she has been. The apathetic indifference of the commercial and manufacturing classes to India is no doubt due to their ignorance of the real character and capabilities of that great country. And to their consequent inability to appreciate the enormously valuable services she can render to us, in return for equally important services rendered to her. She is especially and peculiarly an agricultural country, and therefore is exactly what we require as the complement to our manufacturing industries at home. Had her urban population been in the same proportion as ours, her towns and cities would have contained eighty millions of inhabitants, a population larger than that of all the Russian. Now, what is the fact? Her greatest city, Calcutta, is only about 100,000 larger than Glasgow; her second city, Bombay, about 30,000 less than Glasgow; while her third city, Madras, and her fourth city, Lucknow, require to be added together to be equal to the queen of the Clyde. These four cities, with all the other important cities of India added together, do not contain so many inhabitants as London. The people of India are to be found, not in cities and towns, but settled on the land; and it is computed that nearly 97 per cent. of the population depend more or less directly on the produce of the soil. But that produce, however cheaply grown, is of no value to the Indian farmer unless he can find a market for it, and no market can be found without railways. Sir James Bain says that within a few hundred miles of Calcutta, grain is offered at fabulously low prices without finding a sale, simply because there is at present no suitable means of transit to the great consuming markets. Now, suppose we were to begin in 1884 to make 2,500 miles of railway in India under Government guarantee, and to continue the process for five years to come, what would be the result? In the first place, we should send out to India about 500,000 tons of railway material annually; in the next place, the railway extension would bring every year additional millions of Indian cultivators into profitable connection with the markets of the world; and the outcome of the five years' programme would be that India would thrive as she has never thriven before; that she would become by far and away our best customer; and that the energies of the shipping, the manufacturing, and the iron industries would be taxed to the uttermost to meet the legitimate and growing demands of our Eastern Empire."

We observe with much satisfaction that the mining enterprise of Mr. W. O. Law, of Moulmein, in the Salween district, has succeeded beyond expectation. A correspondent writes:—"We shall have between two and three thousand tons by the beginning of the rains. The want of this country is roads and population. The Salween district, where the mines are, is a dense jungle, trees, nothing but trees, for days and days, miles and miles, trees *where men ought to be*, and this all because there are no roads and the waterways are so bad. The enormous fortunes in minerals and woods here exceed belief, could one only get at the places; but the forests are all wrapped in the silence of perpetual desolation, that is, as far as *men* are concerned, with here and there only a few miserable Karens in villages of 8 or 10 huts."

THE outlook for those interested in the rice trade of Burmah is not particularly bright. Most millers have lost enormously by their operations this season. At the commencement, judging from home prices, low rates were looked for here, and an attempted co-operation amongst buyers to keep down prices was started, but owing to the state of commercial morality did not last 48 hours. The Burmese cultivators in the district withheld supplies, and in consequence prices of paddy have gone up from Rs. 70 to Rs. 95, leaving an enormous loss on contracts for delivery of rice entered into, taking the former rate as the standard price. I am told that in the district people hold large stocks of their own, and bought paddy which did not cost Rs. 40, and for which they now refuse Rs. 80. I am

afraid that this Burman tendency of not being satisfied with a good profit when available, will result in great loss to many holders who seldom make good arrangements for storing for any length of time. When the rains set in, towards the end of May, it will be found that much of the stored grain has been placed on low ground, where it is sure to get damp and heated, and will then be useless. And thus much of it, which could be sold profitably now, to yield at least Rs. 80 per hundred bushels, will be unsaleable except at a loss three months hence, if indeed it is saleable at all. In Rangoon itself, some mill owners are reported to have lost from 2 to 3 lakhs of rupees on their contracts this season, whilst, owing to the non-arrival of grain from the districts, many vessels have come on demurrage, occasioning great loss to their charterers. The outlook is indeed a gloomy one, and both buyers and sellers have themselves to blame. The former were foolish in trying to work together to reduce rates, and then in some instances cheating each other by allowing their brokers to pay extra rates, or to permit the baneful system of short measurements, for which the Rangoon paddy trade has acquired an unenviable notoriety. The sellers again, when they found they had the best of the bargain, and could realise a handsome profit, are foolish in holding on simply with the faint prospect of making those profits larger. They may find that they are killing the goose for the sake of the eggs, and that by their action they have so disorganised the rice trade that they may end in diminishing the number of future buyers, and thus reducing competition for their produce, whilst their arrangements for a "corner in rice" are of such a primitive nature in the districts that I fear it will be found eventually that many thousand tons of the 1883 crop will become damaged and unsaleable owing to bad storage, and thus a large quantity of food will go to waste, and the rest of the world be deprived of it through buyers and sellers in Burmah being unable to conduct their business on amicable terms.

Mr. JOHN ALGERNON CLARKE, the Secretary of the Institute of Agriculture, recently founded in South Kensington, London, calls the attention of farmers' sons and daughter to the advantages provided by the institute. Could the Government of India derive no hint from such an institution? Mr. Clarke says:—Our technical lectures, illustrated by diagrams, models, specimens, and apparatus, on poultry management, dairy management, and bee management, are so arranged that two lectures daily enable the whole course on each subject to be compressed into twelve days, while to attend all three courses requires a visit to London of under six weeks. Thus the advantage of almost a whole college term is afforded in a very brief period of practical instruction. The fee for each course of twenty lectures is only one guinea, or three guineas for all three subjects. A ladies' committee will aid female students in the selection of suitable lodgings.

The instruction in poultry management is given by Mr. W. B. Tegetmeier, F.Z.S., from March 28 to April 6, with an examination on April 7 for certificates of merit; the instruction in dairy management is given by Professor J. F. Sheldon and other experts from April 9 to April 20, with examination on April 14 and 21; and the instruction in bee management is given by Mr. F. Cheshire from April 23 to May 4, with an examination on May 5 for certificates of merit. The lectures are given at half-past ten and at noon in the morning of each day, in the lecture theatre of the South Kensington Museum. Simultaneously a series of eight evening lectures is arranged for guinea subscribers and their friends, while special arrangements are made for the admission of school teachers. I shall be happy to send full particulars to any of your readers who may apply to me.

The exports of grain from South Australia last year amounted in value to 4,187,840*l.* against 3,643,402*l.* in the previous year. The combined import and export trade was 12,067,000*l.* against 9,632,000*l.* in 1881. The wine exports have increased from 20,000 gals. in 1880 to 48,000 gals. in 1882.

The Provincial and Dominion Grangers have been holding their annual meetings in Toronto. This order, which is purely agricultural, and in fact is not open to any but bona fide farmers, has made great strides during the ten years of its existence. There are now in the Dominion 883 Grangers organised into fifty-five divisions. These societies appear to be doing a good work in promoting a desire for mutual improvement among farmers, and bringing many important questions to the front which could only be taken up in this way. It appears that seven-tenths of the inhabitants of the Dominion belong to the farming class; and the desire for further representation in both branches of the legislation was expressed by several speakers. Scientific farming is reported as having come much into vogue of late years, and is traced to the beneficial effect of these country Grangers. Altogether the order is in a flourishing condition, and seems to be doing a good work.

The following is from the *Colonies and India*:—Among the thousands of emigrants who annually leave our shores to carve out for themselves new homes in the backwoods of our various colonies, there must be a considerable number who at some time or other have cause to regret the incautious use of the axe or other tools, whereby wounds are unintentionally inflicted when far from medical aid. Under such circumstances the knowledge of some simple, cheap, yet efficacious styptic might save many a life, or at least hasten a tardy convalescence. In John Tradescant's garden at Lambeth, during the days of Charles I, there flourished one plant whose merits and uses, if then known, seem speedily to have been forgotten. But this plant, *Tradescantia erecta*, a native of Mexico, although possessing nothing attractive in either shape or colour, deserves to be inscribed in every emigrant's note-book on account of its extraordinary efficiency in arresting the flow of blood from wounds. When Mexico was visited by a French army some years ago, a native suggested that the commanding officer, General Martroy, should store in his camp a supply of what he described as "the blood-staunching weed," which proved to be the same plant to which the English king's gardener in 1629 gave his name. On his return to France, the General, having brought some specimens with him, planted and cultivated them at Versailles, and enjoyed the satisfaction of finding the plant taking kindly to the soil, and retaining all the original styptic properties attributed to it by the enthusiastic Mexican peasant. Indeed, its power of suspending hæmorrhage, on being crushed or chewed and applied to a wound, is said to surpass every hitherto known means. The Vienna press has lately been strongly advocating its regular cultivation, and the suggestion might well be adopted in other countries. The plant is easily cultivated, and would no doubt thrive in both our tropical and our temperate colonies.

Six years ago last July, S. J. Arnold & Bro., in the famous Nuces canyon, commenced with 875 goats and 1,400 head of sheep. Now they have 4,000 of the former and 8,000 of the latter. Their losses in sheep will amount to about the same in money value as their purchases, while on the goat question they are \$3,000 ahead of their losses, besides their increase. During this period their losses from disease and otherwise have not been over two per cent on their goats. They have run seven different flocks which give steady employment to seven herders, besides a vicero (who superintends flocks), as well as extra hands to attend to other work on the ranch. In the shearing, lambing, and dipping seasons of course the number is greatly augmented. On this ranch the goats have been improved up by the best of thoroughbred billies until now the grades run from one-half to fifteen sixteenths. Last spring their goat clip amounted to 1,200 pounds, which was sold in New York at an average of 40 cents. In common goats the profit lies in the hides and tallow, which always command a good price, and the supply of good meat in a shape that will not spoil in warm weather before it can be used up. By using Angora sires a flock can be graded up so high that the wool is more profitable than that of sheep, and the animal itself is harder, more prolific, and less expensive.—*United Harrier*.

According to the *Moniteur des Filés et Tissus*, a report on flax has been sent to the French Government by its Consul at New York, from which it would seem that the cultivation of flax (which was almost unknown in the United States at the commencement of the present century) has of late years acquired a certain importance. There are now more than a million acres devoted to flax-growing in various parts of the Union, Iowa occupying the leading position with about 300,000 acres, Indiana following with about 200,000, while Illinois and Kansas each furnish about 160,000 to the total. Ohio, Minnesota, Wisconsin, Missouri, and Nebraska show a joint total of about 320,000 acres. From this extent of land under cultivation, it would at first sight seem that the production of flax is sufficient to meet the domestic requirements of the Union; but it is remarked that the inexperience of the growers, and the inferior quality of the seeds used, have combined to limit the advantages which might be derived from this abundant culture. An authority on the subject has stated that farmers owning 450,000 acres are obliged, for the want of suitable outlets for the fibre, to burn it, and only to preserve the seed. The protection afforded by the tariff to the domestic industry has to be considered; and it is further asserted that two large Irish firms, who have recently established factories in New Jersey, are obliged to import the bulk of their requirements of the raw material.

The cause of this state of things has been attributed to the low price to which native American flax was driven, when the reduction of the jute tariff opened the American markets to large imports of the Indian fibre. The indigenous article would seem to have been employed at one time rather extensively in the manufacture of bags and of coarse tissues. The circumstances alluded to brought about a depreciation of value, which has discouraged farmers from giving the needful attention to the much-needed improvement of flax culture.

It is suggested that if a proportion of the immigrants now arriving on the shores of America were to be put in the way of growing flax instead of wheat, &c., there would be more chances of success for those who have already been giving their attention to cereals. In this way, it is remarked, an improved quality of flax might readily be acclimatised in the Union, and, under the climatic advantages it enjoys, the New World might be reasonably expected to produce those supplies which have now to be imported.

At a recent meeting of the State Fair held at Utica, New York, Dr. Sturtevant, Director of the State Experimental Station, propounded a novel method of cutting seed potatoes for planting. He remarked that when a potato is planted in its natural condition, only two, three, or very rarely four of the eyes vegetate. He maintained with elaborate illustration of argument, based on experiment in germinating potato tubers, that a single eye has the capacity of originating all the potatoes that a whole plant ought to be expected to bear. He stated that the first absorption which takes place in the planted tuber is within definite lines, which lines may be distinctly seen by uplifting the potato, and soaking it in carmine water, when it will be seen that a line of vital tissue runs through the centre, with a branch running to each eye. Tubers may form anywhere on these lines, as the life of the potato is not confined to the eyes, for a whole potato, after the eyes have all been destroyed, will sometimes develop a new one inside the old one, without any outward vegetation whatever. His instructions for planting are—Cut out each eye deep to the centre of the potato at a certain definite angle, to be ascertained by experiment with carmine water—doubtless other colouring matter, such as most of the aniline dyes, will do as well—and you will get the maximum yield and the best quality of produce from that eye. Trials of this plan have been made at the State Experimental Station, of which Dr. Sturtevant is the director, with the following results:—A hundred hills were planted in rows a foot apart. Where whole potatoes, or halves, or quarters were planted, there was no sort of uniformity in the yield, whilst the crops of adjoining hills varied as much as

three to one. Where single eyes were planted out according to the new method, so as to preserve the axis of the eye, the product was surprisingly uniform in all the rows. In every case a piece cut deep, however small the portion may be, gave a better yield and quality than when a large piece was cut shallow. He maintains that by cutting potatoes in the manner described, the yield may be increased at least 25 per cent., whilst a great saving is effected in the quantity of seed potatoes required to plant the allotted ground.

The great money crop of Western North America is stated to be Indian-corn.

Among our selections will be found a paper by Professor W. A. Henry on planting and cultivating northern cane. While some of the suggestions may be unsuitable for India, others, we hope, may be valuable.

The following analysis from *The Colonies and India* of the Export Trade of Britain is compiled from the monthly account published by the Board of Trade relating to the United Kingdom during February 1883. It exhibits, in as clear and full a manner as circumstances will permit, not only who are Britain's best customers, but the character of the business transacted with them. It is hoped that by this means our readers will be put in possession of information as to the course of trade in its different branches that will prove of some practical service:—

Many of the entries of exported articles are rendered in these accounts in terms so general that it is impossible to include them in the above tabulated statement. The more important of such entries are set down as follows:—Animals, 21,756*l.*; arms, ammunition, and military stores, 104,235*l.*; manufactures of brass, 37,608*l.*; candles, 10,270*l.*; butter and cheese, 14,713*l.*; manufactures of India-rubber, 84,278*l.*; carriages of all kinds, 70,413*l.*; chemical products, 149,357*l.*; lace and patent net, 321,158*l.*; hosiery (cotton) of all kinds, 106,019*l.*; thread for sewing and stitching, &c., 180,717*l.*; fish, 5,933*l.*; glass—plate, mirrors, flint, bottles, &c., 75,022*l.*; hats of all kinds, 96,190*l.*; leather, unwrought, 115,096*l.*; pickles, vinegar, sauces, condiments, confectionery, &c., 90,278*l.*; plate and plated and gilt wares, 18,461*l.*; salt, 31,180*l.*; soap, 37,809*l.*; telegraphic wires and apparatus connected therewith, 22,738*l.*; tin, unwrought, 37,777*l.*; flannels and blankets, 95,658*l.*; and hosiery of wool and small woollen wares, 98,982*l.*

The enumerated articles represent a value of 16,470,210*l.*, in addition to which there are articles set down under the head "nonenumerated" valued at 1,810,600*l.* The total declared value of British and Irish produce exported during the month of February last is 18,380,810*l.* The figures for the corresponding period last year were 18,935,994*l.*; while for February 1881, they stood at 16,835,560*l.* The total declared value of exported articles during the two months ended February 28th last amounts to 38,889,469*l.*, whereas the returns for 1882 were 38,756,677*l.*, and for 1881, 34,154,461*l.*

The following agricultural statistics from a paper read before the Society of Arts by Mr. Delisle Hay may be useful:—

Last year—1882—there were in the colony of New Zealand 3,638,069 acres under sown and cultivated grass;

1,002,485 acres under various crops; of which 365,715 acres were under wheat, 304,818 acres under oats, and 22,808 acres under barley. You thus see what a very small proportion (about 1-12th) of even the first-class agricultural land has yet been brought under crop. There is an impression prevailing in England that New Zealand is getting crowded, as far as the farm lands are concerned, and that not much is left available to agriculturists. No doubt it has arisen from the fact that the Crown lands in the South Island are mostly disposed of. But this is not to be taken as implying that you cannot now buy land there; you can certainly do so; but you buy from private owners, and, of course, at an advance upon former prices. Nor does it imply that the land disposed of by the Government has all been settled, and taken up. This is far from being the case, putting aside the question of the wide tracts leased as cattle-runs and sheep-walks.

I am desirous of proving to you, said Mr. Hay, the enormous capability of New Zealand as a wheat-raising country, and the possibilities of the future in regard to this item. The industry is yet in its veriest infancy, but enough has been done to show what may, and will be, accomplished in coming years. From the returns of last autumn—that is, February 1882—I quoted 365,715 acres as being the total area in the colony under wheat crops. The yield was 1,037,236 quarters, giving an average of rather more than 22 bushels per acre. The previous year, New Zealand had exported 670,157 quarters of wheat, value £745,729, nearly the whole of this being sent to Great Britain.

The New Zealand farmer has already begun to enter into competition with his fellow of Manitoba and the prairie lands of North America, in supplying us here with corn, though what he has so far done be only an index of what he will eventually accomplish. 365,715 acres under wheat has served for a foundation to the grain trade: but this extent is only a tithe of the 12,000,000 acres—at least—which are suited for the corn-raiser. It is profitable now to the New Zealand cultivator to send his produce to Great Britain, in spite of present disadvantages. But when transit across Panama is rendered feasible, the cost of placing wheat on the London market should be lessened from the 1*s.* 8*d.* per bushel at which it stands at present, and the profits of the grower will be consequently greater.

Corn-raising in New Zealand must be considerably more advantageous than in North America. The virgin soil of the colony returns an average crop of twenty-two bushels per acre, about double the average of the prairies. An average of thirty to forty bushels has been reaped in some districts, and ninety bushels of oats has been known. Then, having no severe winter to contend against, the New Zealand farmer can generally utilise his land for a second crop of roots or other produce, and can also make use of straw. His crop is also far heavier than what is raised in Australia, where, moreover, droughts often render wheat a failure. He has a home market, and an Australian market, besides an English one.

It is in the south-eastern part of the South Island that most farming has yet been done. By far the greatest part of the land now in cultivation is located here, and the production of other districts has been slight, as compared with the production of this. This applies to the present only, though, for the North Island, and the northern section of the South as well, will show substantial returns by-and-bye.

Agriculture is being more and more largely resorted to in all the counties of the south-east section, grain and other crops being raised in all. But the chief wheat-growing counties as yet are Ashley, Selwyn, Ashburton, Geraldine, Waimate, Waitaki, and Southland. Still, in Waikomiti, Taieri, Tuapeka, Bruce, Clutha, Lake, and Wallace, agriculture is promising, and large harvests of corn will yet be reaped in them also. The stockman and shepherd are here giving way to the steam-plough, just as the export of wool and tallow and hides is being encroached upon by the demands of local manufacturers.

The New Zealand of the future will be a country exporting her own manufactured goods rather than her raw produce. The beginnings of this are already evident, and, as we might expect, are chiefly apparent in the Otago and Canterbury districts. Take the item of wool, which, as you know, has been one of the main exports of the colony. In 1880 the quantity exported was 66,860,150*lb.*, value £3,169,300. There was a

slight decrease the following year. But there are now four woollen factories at work, soon to be followed by others. The aggregate valuation of their plant is £100,000, about, and they employ 417 hands. The factory at Mosgiel, near Dunedin, is turning out tweeds that already have a considerable repute. In 1881 the profits of this establishment were £6,900, giving a ten per cent dividend to the shareholders. There is a reserve, too, of £10,000. At Roslyn, a suburb of Dunedin, there is another woollen factory, which cost £60,000, for buildings and machinery. In the rapidly rising town of Oamaru there is another. The fourth is at Kaipoi, in Ashley county. This last has 1,440 spindles and 30 looms, and it is said that it can turn out 1,000 pairs of blankets, and 6,000 yards of flannel per week.

These figures may not seem very large, perhaps; but Manchester and Glasgow had small beginnings too, and the development of manufacturing centres in New Zealand will be more rapid, because of the increased facilities procurable in these latter days. Wool and woollen manufactures have the most important bearing on the future country. It is doubtful if the wool-growing capacity of the colony has reached anything like its ultimate maximum. The great sheep-walks of natural pasture must certainly diminish year by year, as agriculture is more resorted to. On the contrary, land at present covered with useless fern and scrub, or with forest, annually yields a larger and larger area to the settler, which is broken up and put under grass—made into meadows and paddocks, in short; and this will feed more sheep to the acre than the other; so that the flocks may be even increased in number, although the present pastures be more encroached on by the plough.

CONSUL McLAIN states that, next to the pine-apple business, the trade in sponges is the most important industry of the Bahamas, bringing considerable gain to the colony, and furnishing steady and lucrative employment to several hundred vessels and several thousand persons. At first sponges were divided into only two classes—the coarse and the fine, the former realising about twenty-two shillings a hundredweight, and the latter about double that sum. They are now, however, divided into many varieties, among the best known being, “sheep wool,” “white reef,” “abaco velvet,” “dark reef,” “boat,” “hardhead,” “grass,” “yellow,” and “glove.” The vessels engaged in sponging are small craft, of an average burthen of ten tons, each vessel carrying from six to twelve men. They are furnished with about six weeks’ provisions, and coast along the banks and reefs where the water is shallow, and among the islands where the sponge is known to exist. The sponges are seen growing upon the rocks, reefs, and shallows, the water being particularly clear, and they are brought to the surface by means of iron hooks, fastened to long poles, or by diving. When first taken up, they are found to be covered with a soft gelatinous substance, full of life, and perfectly black, the sponge proper being but the skeleton or support of this living organism. The day’s catch is spread upon the deck so as to kill this living covering which, in decaying, emits a very disagreeable smell.

When a sufficient quantity of sponge has been gathered, the boats are taken in shore, and a pen or hut of stakes is made on the beach, at the water’s edge; the sponges are placed inside, when the action of the tide helps to remove the black covering, the process being completed by pounding them with sticks. Having been cleansed in this manner the sponges are strung upon small palmetto strips, each string containing three or four sponges, being called “bead,” and with this cargo the vessel returns to Nassau. A cargo will vary from £15 to £16, according to quantity, quality, and demand. The sales and handling of the sponges are controlled by the Nassau Sponge Exchange Company, an organisation holding a charter from the Colonial Legislature. The company has erected a commodious building upon one of the wharfs; and it is in this building that all the sponges are sold, subject to certain taxes and restrictions. As soon as the daily sale is concluded, the sponges are taken away to the packing yards, where they are assorted and clipped into good shape. They are then put into tubs or vats of lime-water to soak for several hours, and

are afterwards spread upon canvas to bleach and dry in the sun.

They are next pressed by machinery into bales about three feet by two feet in size, each containing 100lb., the packages being covered with coarse bagging, securely sewed and corded, and are then ready for shipment. All the work in connection with the sponges, from the taking to the shipment, is performed by the blacks. There has recently been discovered, Consul McLain says, a new and extensive field of sponges near the island of Eleuthera, only sixty miles distant from Nassau; the water, however, on this new field is from five to eight fathoms in depth, and this has the effect of rendering the gathering of the sponges tedious and laborious. It is thought that the field is a very extensive one, stretching over many miles, and that the sponges are, as far as known, all of the “sheep wool,” or most valuable description. The majority of the sponges found up to this time are of a very large size, and will not bear cutting to advantage, as the inner portions appear to be very tender.

During three months of 1882, this field was actively worked, but a sudden interruption has occurred, caused by the fact that myriads of small fish have invaded the grassy bottom, stirring up the mud to such a degree that it prevented the sponge from being seen. It is the opinion of fishermen who have been engaged for years in this industry in the Bahamas, that the sponges can only be gathered in any quantities in this field during a portion of the year when the water is still and the fish is absent. This would detract very considerably from the value of the discovery. It appears from statistical returns of the imports and exports of the Bahamas that there is a very large increase in the annual exports of sponges, the value in 1881 amounting to about £38,000, or nearly twice as much as in 1874.—*Journal of Society of Arts.*

MR. L. GIBBORNE SMITH, in the *Indian Forester* for April, has the following:—“I notice in your vol. IX of January 1881, an article by Mr. Gamble, containing a list of tea-box woods used in Darjeeling. He concludes his letter by asking some one to furnish a list of the woods used in Assam and Cachar. As the tea industry is not confined to Bengal and Assam alone, I would suggest a general list being compiled of all the woods used for making tea-boxes in various presidencies and provinces throughout India where it exists.

To further this suggestion, I send you a list of tea-box woods used by the planters of the Kangra district, Punjab—

| Rai | ... | ... | <i>A. Smithiana</i> (called <i>Tos</i> at Palampore). |
| Tos | ... | ... | <i>A. Webbiana</i> (called <i>Rai</i> at Palampore.) |

These are chiefly used, though there are several other woods which I have no doubt would answer the purpose, such as alder, elm, poplar (phalse), hill tun, and chil. Deodar is not used for tea boxes owing to its strong smell of turpentine.

I hope to see the general list added to.

I know, says Mr. George W. Pascal, from practical experience that M. Bourlier and M. Hervé are quite correct as to the value of diseased potatoes as an article of food for cattle, pigs, &c., but the most important item to be observed they omit in their directions, which I revise as follows:—

Boil the diseased tubers fast till done; drain, and let them become perfectly dry by spreading them out on sieves—a gravel screen is the best. The tuber, when cooked, is free from poison; the water in which it is boiled is a very strong poison, and will scour, if not kill, any animal that partakes

of it. When dry, ram tight into any kind of dry cask (with salt), and keep in a cool place till wanted. One copperful can be dried and packed while the next is cooking, so that a large quantity can be cooked in one day. Every farmer should know this, as it would save him suffering any loss, however bad his crop might be.

It appears that the success of the Ahmednuggur horse and cattle show and agricultural exhibition held at Nagat in August last has exceeded all expectations. The results of the exhibition, so far as regards the horse show, have brought to notice the fact that many excellent mares are to be found in the district, and the Bombay Government is, therefore, of opinion that considerable improvement may be effected in a few years in the breed of horses through the services of the Government stallions. We observe that mule-breeding is also said to be making progress, and prizes were awarded at the exhibition to the owners of all mares proved to have been covered by donkey stallions. Some of the excellent bulls exhibited by the Khandesh farm were bought up at the exhibition, and it is believed that their purchase will lead to an improvement in the quality of the cattle of the district. The agricultural part of the exhibition, too, was very successful. Some samples of excellent wheat were brought from parts of the district, and it is trusted that the exhibition will have the effect of stimulating the production of the better classes of grains. In connection with the Ahmednuggur horse and cattle show, we observe that it has been decided to discontinue the horse show at Sirur, which is near both Poona and Ahmednuggur, at both of which places horse shows are held. This will have the effect of making the Sirur exhibitors bring their cattle over to either the Poona or Ahmednuggur shows.

In consequence of the early setting in of the rains, the *khari* season of 1882-83 in the North-Western Provinces does not appear to have been very favorable for canal irrigation, although the area irrigated during that period was 739,410 acres, or 33,885 acres in excess of the area of the preceding year. The principal crops irrigated were sugarcane, rice, bajra, and juar, maize, fodder crops, fibres, and dyes. The increase of 33,885 acres occurs chiefly under sugarcane, maize, dyes, and miscellaneous crops. The total area of 739,410 acres was irrigated in the following proportion by the different canals of the provinces:—

| | Acres. |
|------------------|---------|
| Upper Ganges | 335,570 |
| Lower do. | 199,115 |
| Agra | 52,263 |
| Eastern Jumna | 112,483 |
| Rohilkhand | 32,863 |
| Djm | 5,520 |
| Bijnour | 1,678 |
| Hameerpore Lakes | 70 |
| Jhansia | 42 |

MR. W. COLDESTREAN has written a very valuable note on the encouragement by Government of private efforts by zemindars in tree-planting in the Hoshiarpore district, which we give in its entirety:—

"Captain Montgomery's recommendation, that zemindars should be encouraged to plant on the edges of *chohs* or sandy torrents, I entirely agree with. Plantations in such situations would have the best effect, and an effort in this direction is the proper and necessary complement to reboisement operations in the hills now under consideration. The useful action of plantations in stopping the encroachment of *chohs* cannot be doubted; and it is a fortunate provision of nature that the *shishum* tree grows particularly well in the sandy soils of this district, and a plantation will spring up in most unfavourable-looking tracts in or near the beds of *chohs*.

"The value of a belt of trees or plantation in stopping sand drifts, of *urdr ret*, as it is now generally termed, is obvious.

"I think Captain Montgomery's proposal as to terms is appropriate, but I would be inclined to limit the concession to the term of settlement, when the plantation is formed on land actually assessed to revenue.

"I think also that Captain Montgomery's proposal to except fruit-trees is proper; and I also agree that the rules should not

have retrospective effect. I understand that Captain Montgomery proposes that when the land is unassessed, a remission of revenue on an area equal to half of that of the plantation should be allowed. I think this will be all that is needed. The plantations should be subject to supervision by the District Officer, who should have the power of cancelling the grant when the plantation was not properly looked after when young, when the trees were cut down too soon, or too many at once, or when trees cut down were not replaced by fresh saplings. And the grant should not be made till the District Officer is satisfied that the trees are not only on the ground, but in a fair way of doing well, and growing up into a plantation. This would ordinarily be in the second or third year after the trees were planted or sown.

"But there is another direction in which I think that village plantations should be encouraged, and much might be done by judicious encouragement at settlement.

"Captain Montgomery's proposal is specially aimed at defending village lands against *choh* action, and this is doubtless the direction in which Government has most to gain from village arboriculture. But I also think that village groves and plantations on a large scale might be beneficially encouraged without special regard to their utility as defences against the torrents. There are in this district, in the plains as well as in the hills, villages of enormous area, containing *shumilat* lands, generally no doubt of an inferior description of soil, but quite suitable for tree planting, and capable of bearing most valuable plantations of *shishum* and other trees; such as *burr*, *kikar*, *dhat* or *palas* (*Butea frondosa*), *burr* (*Ficus indica*), and others. There can be no doubt that many villages have tracts of land in excess of their grazing requirements, and that even if plantations prevented the growth of grass, they might have a much more remunerative product in trees. The grass on many of these *shumilat* lands is of exceedingly poor quality, such as it would hardly be a loss to abandon. But I believe that the growth of trees on many lands, if they were not planted so as to be crowded together, would not only not destroy, but improve, the grazing, and thus secure a double benefit to the village. It is quite unnecessary here to say anything about the value of trees to the villager in particular, or of large areas of plantation to the country in general. Villagers are now beginning, as mentioned by Captain Montgomery, to appreciate the benefits to themselves of tree planting, and many plantations of trees other than fruit trees are to be found throughout the district. But they want, I think, two helps. They need to learn, and have it constantly impressed on them, that trees will not grow properly unless the area in which they are planted is thoroughly fenced in, and for the first five or six years kept free of cattle and goats. Secondly—and here it is where I think a grand opportunity presents itself during settlement—they need to be encouraged to combine, as proprietors, to rear communal plantations. I believe that they know their own interest quite sufficiently to be willing and even eager to enter into a scheme of the kind if the Settlement Officer will be so kind as to show them the way. What they sadly lack is capacity for corporate action. This capacity, I conceive, could be developed and stimulated by a very little aid on the part of the Settlement Officer; and when the administration paper is drawn up, an excellent opportunity presents itself. They would, I am convinced, in many cases be most willing to set about making common plantations if, first, they were only shown the right way to set about it, and secondly, were assured and became convinced that Government had no wish to interfere with their rights in the land or trees to be raised on them.

"What I should propose is that when there is any large area of common land, the proprietors should be encouraged to enter conditions in the administration paper relative to

| | |
|---|---|
| Fencing, Planting or sowing, Tending, Protecting, And in due time grazing in, and cutting wood in, | } A communal plantation or plantations. |
| | |

"The rules need not be long, and might be very simple. Under present circumstances any proprietor, who was progressive enough and sufficiently public-spirited to propose making a common plantation, would encounter a hundred difficulties in the

apathy of some and the jealousy of others of his fellows. But if rules on these points were drawn up in council under the supervision and at the instance of an official of influence, the ice would be broken, and official sanction would afford the necessary stimulus in a direction to which they would feel that all their own interests tended."

An esteemed correspondent writes to us: "The Nagas in this portion of the Naga Hills (above Amgourie tea garden), are getting a good deal of rubber from a woody vine. The vine climbs trees and grows to three or four inches in diameter. When the seed-pods are ripe, they burst open, and a light slimy material comes forth, and is wafted about by the winds. It is this fact that gives to the vine its Naga name *Apungmango*. The botanical name I do not know. The vine is common in the forest jungle of these hills, and the Nagas say it is in the forests at the base of the hills, but not as abundant as in the hill forests. The juice in the green state and when dried has every appearance of that from the rubber tree. It might be well for Government to ascertain how abundant this forest vine is in the plains and other hill districts of India: also to give a thorough test of the value of the rubber from this vine.

From the report on forest administration in Coorg for the year 1881-82, we learn that the total area of the reserved forests at the close of the year stood at 234 square miles, or 149,865 acres. There were no additions made to the area of the reserves during the year under notice. The work of demarcating the ghat forests was completed, and 63 miles of new line were opened up at a cost of Rs. 6 per mile. We observe that it is intended to depute a settlement officer to go over the line thus demarcated, with the object of settling any claims which the ryot may advance as to the inclusion in the demarcated area of portions of land belonging to private individuals.

The results of the attempt to protect the forests from fire during the year under notice do not appear to have been as successful as in previous years. Out of the total area of 123,049 acres which it was attempted to protect, only 46,556 acres were successfully conserved at a cost of Rs. 1,417; the failures amounted to 76,493 or 62.16 per cent of the so-called protected area. The fires appear, it is said, to have been caused by shikaris and kurumbars, and are attributed to a want of vigilance on the part of the forest guards. We observe that some difficulty has been felt in working the remote and inaccessible ghat forests, owing to the extensive timber thefts committed by license-holders, who felled much more wood than they were entitled to. To remedy this, it was determined to lease the forests to respectable contractors, but the results have not been satisfactory, as the contractor to whom the Urti and Kerti forest was leased, has failed to make it pay. The local administration, it appears, now propose to work the forests departmentally, and this is to be done at first on a small scale.

An area of 109½ acres was added during the year to the plantations already in existence, which measured in the previous year 327½ acres. The planting operations generally are said not to have been very successful owing to scanty and unseasonable rainfall; while the rearing of teak in plantations is also reported to have been not very satisfactory, in consequence of defective methods adopted in sowing and planting. There were 21 cases of breach of forest rules prosecuted during the year, of which 14 cases resulted in convictions, and 31 persons were punished.

The financial results of the year are given as follows:—

| | | | Ra. | A. | P. |
|--------------|-----|-----|----------|----|----|
| Receipts ... | ... | ... | 1,00,363 | 12 | 4 |
| Charges ... | ... | ... | 59,858 | 1 | 1 |
| Surplus | | | 40,505 | 11 | 3 |

Compared with the income of the foregoing year, the receipts have increased by Rs. 12,507, the excess being attributed to large sales of timber, and to heavy fines imposed on timber stealers. Only 60½ tons of sandal-wood appear to have been sold during the year instead of 120 tons, the annual quantity fixed for sale. The decrease is due to the small quantity of sandal-wood sold, the

authorities refusing to sell the remainder owing to the low rates offered. The merchants, it is reported, have combined to keep the rates down; and the small quantity of Coorg sandal for sale has of late failed to attract richer and more respectable merchants, especially as the neighbouring province of Mysore has been supplying much larger quantities of sandal to the market.

An American paper says:—The enormous amount of jute bagging used in the United States, and especially in the South, where it is required for covering six million bales of cotton annually, directs attention to this article as a staple of great importance and value to the people of this country.

Jute, as is well known, grows luxuriantly, and can be produced with little trouble and expense in the Gulf States, but the difficulty of preparing the staple for market has been the great obstacle in the way of its adoption as a Southern agricultural product. The jute of commerce is grown in India, and is there prepared for market by the cheap hand labour of the natives, and as a consequence the Southern planter, at the rate he is forced to hire labour, cannot grow and prepare the fibre so as to compete with the Asiatic producer. Attempts have been made to use mechanical contrivances for separating the fibre of the plant from the woody matter of the stalk, but heretofore no satisfactory results had been secured; but now a new machine for separating and preparing the jute fibre has come to public attention, and, as far as it has been tested, it appears to have accomplished the solution of a most important problem. Details of experiments with this machine are given in another column, in a letter from Col. Daniel Dennett. He presents an interesting account of the working of the machine at the Menelas plantation, near Brookhaven, Miss., on Friday, October 27th, when it was employed upon green jute stalks just as they were cut from the fields. The results given are said by Mr. Dennett and other gentlemen to be excellent. So effectually did the machine do its work, that Mr. Smith, the patentee, who was present to test its operations, declared that it would prepare jute fibre for market at a total cost for production and separation of 2 to 2½ cents per pound, when the imported article is selling in the markets of this country at 4 to 4½ cents a pound, an unusually low price by the way, but one nevertheless which will pay a handsome profit to the American producers.

With these results assured, another great industry is likely to be opened to the Southern planters, and vast areas of lands in Louisiana and other of the Southern States will be available for its development; but the matter will not stop with the production of jute. The ramie will follow logically. The need of machines that will properly and profitably effect the preparation of the ramie fibre, will doubtless be supplied as effectually as for the jute. The Whitney gin created the cotton industry. It remains for another genius to bring the jute and ramie fibres to a front rank in our textile productions. Let us hope this grand result is now about to be realised, and that other great industries are to be opened up to the rich lands of lower Louisiana and the whole Gulf coast.

The *New York Experiment Station Bulletin* has the following note on milk:—

There is much to be learned yet concerning milk. We know that milk is not a filtration, but is manufactured within each division of the udder, and is therefore variable, according to the working power of each separate factory. We know there is a difference, through analyses of the milk of each teat separately, as such analyses have shown a variation in physical constituents as well as of structure. We also note that what affects the efficiency of the factory, has also a perceptible effect upon the milk. It is this relation between the milk and the cow which causes the dairy cow to exist, and which enables us to say boldly that breed is superior to feed. On account of this structural relation of milk, its secretion becomes influenced by heredity, and the breeder is enabled to add up qualities through successive generations of selection, even as the book-keeper adds up his successive items in the column of his ledger, in order to obtain the total results. The heredity of the wild cow has not been selected in the direction of milk. The cow in a state of nature

yields milk, but in the presence of her calf. The dairy cow, however, the creation of the art of man through the process of selection, has had successive advances in milk-giving added on to each generation, until, unlike the wild cow, the dairy cow yields milk to man, irrespective of the presence of the calf to excite the flow. The wild cow may be fed on the most succulent and milk-promoting foods, and yet she gives no profit to the dairy-man. The dairy cow, however, responds to feed, in milk to a greater or less extent, according to the heredity of the milk secretion which she represents.

Under this condition, we should expect to find phenomenal occurrences in our individual cows, such as excessive yields of milk, of butter, or of cheese; yields promoted either by accidental circumstances, or else through what we must call the accidental accumulations of heredity in some special direction. Thus, in my past experience, I have known the milk of each test of the same cow to vary from 24 to 42 per cent of cream, and one day the milk of a cow which usually only marked from 13 to 15 per cent of cream, gave distinct definition of 60 per cent of cream. Thus, some Jersey cows have yielded as much as three pounds of butter a day, or more; thus some cows have a record of rising 100 pounds of milk a day for several successive days.

From a recently issued circular of Messrs. Ohlendorff & Co., we quote the following:—

The one mineral element to which too little attention has been directed in practical agriculture is potash.

In most stiff soils there is sufficient available potash to support the drain of numerous crops, especially of crops whose roots penetrate some depth in search of food; on the other hand, in most shallow soils of a poor character, in moor lands, and old pasture lands, there is seldom a sufficiency of available potash for the proper development of the crops.

Carefully conducted experiments, notably those of the eminent French chemist, M. George Ville, has proved that a defective supply of potash is fatal to normal growth, even although the crop may have at its disposal plenty of nitrogen, phosphoric acid, and the other elements of plant food.

Some plants require for their harmonious development more potash than others, but all, without exception, require a certain quantity, and where the soil, though well dressed with nitrogen and phosphatic manures, produces disappointing crops, the most frequent cause is poverty of potash. Bearing in mind that the entire quantity of the mineral constituents in plants is only 1 to 3 per cent, about 95 per cent being carbon and water, derived from the air and rain, the following table, showing the approximate quantities of potash and phosphoric acid carried off by the principal crops, demonstrates in a practical manner the important part acted by potash in plant life:—

| A crop of | | contains in lb. | per acre: Potash. | Phosphoric Acid. |
|--------------|---------------------|-----------------|-------------------|------------------|
| Wheat | 5 qrs. grain | ... | 9½ | 15½ |
| | straw | ... | 29 | 11 |
| | Total | ... | 38½ | 26½ |
| Barley | 5 qrs. grain | ... | 11 | 13 |
| | straw | ... | 19½ | 5 |
| | Total | ... | 30½ | 20 |
| Oats | 6 qrs. grain | ... | 9 | 13 |
| | straw | ... | 24 | 4 |
| | Total | ... | 33 | 17 |
| Turnips | 20 T. bulbs | ... | 126 | 31 |
| | tops | ... | 76 | 28 |
| | Total | ... | 202 | 59 |
| Potatoes | 6 T. tubers | ... | 68 | 18½ |
| | haulms | ... | 9 | 3 |
| | Total | ... | 77 | 21½ |
| Hay (clover) | 2 T | ... | 52 | 20 |
| | beans 25 bush, corn | ... | 23 | 24 |
| | straw | ... | 89 | 12 |
| | Total | ... | 112 | 36 |

It is not to be inferred from the table that the application of potash is more necessary than that of phosphoric acid,

because deep soils contain as a rule naturally sufficient potash, and light soils usually a little, whereas almost all soils, both heavy and light, are deficient in phosphoric acid. The figures, however, prove that where there is not naturally sufficient potash, or where frequent cropping has too much exhausted the natural supply in the soil, it is essential to add this constituent.

Probably the best way of supplying potash is in the form of genuine *Stassfurt kainit*, which should contain a little over 23 per cent sulphate of potash, and equal to about 12½ per cent pure potash, and includes also a large proportion of magnesia and soda. The following is a complete analysis of *kainit* by Dr. Aug. Voelcker:—Water, 15·61; sulphate of potash, 23·93; sulphate of magnesia, 17·25; sulphate of lime, 0·95; chloride of magnesia, 14·54; chloride of soda, 27·27; insoluble matter, 0·45—total 100·00.

One cwt. of *kainit* contains just about 14 lb of pure potash, whereas it takes 28 cwt. of farmyard manure to provide the same quantity.

The best time to apply *kainit* is in the autumn or quite early in the year.

It is also found advantageous to occasionally spread a little *kainit* in stables, cattle-yards, and on manure heaps, as the ammonia in the manure is thereby partly fixed, whilst at the same time the percentage of potash and magnesia in the manure is increased.

The following Resolution of the Government of the North-Western Provinces and Oudh, Public Works Department, Irrigation Branch, No. 6181 of 1883, dated the 3rd March 1883, exhibits concisely the work done:—

The kharif season of 1882-83 (from 1st April to 30th September 1882), was not very favourable for cane irrigation owing to the early setting in of the rains. In the beginning of June heavy rain fell in almost all districts, but the break in September caused a demand for water on the Eastern Jumna and Upper Ganges Canals.

2. The returns, however, show an increase of 23,385 in acreage and of Rs. 1,64,584 in assessments over the totals of last year. The total area irrigated during the season under review was 739,410 acres, or 7,825 acres more than the highest ever recorded, viz., in 1877, a year of drought, when the irrigated area exceeded the highest previously attained by 229,960 acres.

The following statement shows in detail the areas of the principal crops irrigated during the last four years:—

TABLE I.

| | 1879. | 1880. | 1881. | 1882. |
|-------------------|---------|---------|---------|---------|
| | Aores. | Aores. | Aores. | Aores. |
| Sugarcane | 165,661 | 185,292 | 164,569 | 197,978 |
| Rice | 75,903 | 135,570 | 101,755 | 96,357 |
| Bajra and juar | 6,635 | 43,286 | 4,141 | 5,104 |
| Maize | 17,265 | 89,274 | 22,376 | 33,411 |
| Other food-grains | 12,535 | 9,207 | 6,887 | 5,982 |
| Fodder crops | 5,966 | 7,924 | 4,554 | 9,930 |
| Fibres | 59,580 | 63,680 | 63,247 | 49,722 |
| Dyes | 185,195 | 194,983 | 319,992 | 316,872 |
| Miscellaneous | 20,871 | 20,943 | 18,504 | 24,354 |
| Total | 555,641 | 700,139 | 700,025 | 739,410 |

Sugarcane has far exceeded the area of last year, and the increase is fairly distributed over all divisions. Rice is slightly under the average of the last three years. The chief falling off is on the Rohilkhand Canals.

The increase in food-grains is due to the large area under maize, which cultivators were compelled to irrigate owing to the break in the rains in September. The increase in this crop alone is 11,000 acres.

3. The items given below exhibit the aggregate differences in the chief crops as compared with the previous year:—

| | 1881-82. | 1882-83. |
|-------------------------|----------|----------|
| | Aores. | Aores. |
| Sugarcane | 164,569 | 197,978 |
| Food-grains | 135,159 | 150,784 |
| Dyes, fibres and others | 406,297 | 390,648 |
| Total | 706,025 | 739,410 |

The rise in the acreage of sugarcane is alone equal to the total increase in the irrigated area on canals, whilst that in food-grains is counterbalanced by a decrease in dyes, &c. The falling off, however, in the latter is not due to any appreciable diminution of the area under indigo, the total under which is 318,993 acres against 319,040 acres last year.

4. Table II compares the irrigated areas of the two years 1881 and 1882, by canals :—

TABLE II.

| Canals. | 1881. | 1882. | More. | Less. |
|---------------------|---------|---------|--------|--------|
| | Acrea. | Acrea. | Acrea. | Acrea. |
| Upper Ganges ... | 296,554 | 335,570 | 39,016 | |
| Lower Ganges ... | 204,572 | 199,115 | | 5,457 |
| Agra ... | 56,497 | 52,263 | | 4,234 |
| Eastern Jumna ... | 104,197 | 112,488 | 8,296 | |
| Rohilkhund ... | 35,922 | 32,663 | | 3,259 |
| Doon ... | 5,315 | 5,520 | 205 | |
| Bijnour ... | 2,894 | 1,678 | | 1,216 |
| Hamirpore Lakes ... | 45 | 76 | 31 | |
| Jhansi ... | 29 | 42 | 13 | |
| Total ... | 706,025 | 739,410 | 47,551 | 14,166 |

The increase on the Upper Ganges Canal is in the four upper divisions, viz., the Northern, Meerut, Anupshahur, and Bulundshahur, which, in round numbers, have extended their irrigation by 8,000, 17,000, 5,000, and 10,000 acres, respectively, over the figures of last year.

On the Lower Ganges Canal the falling off is entirely in the two old divisions, the Cawnpore and Etawah, owing to short supply in the river in the early part of the season. The new divisions taken by themselves show a slight increase, 74,800 acres against 66,527; and this might have been greater had there been more water available for the tail portions.

The principal crops in these new divisions compare as follows :—

| Crops. | 1880. | 1881. | 1882. |
|---------------|--------|--------|--------|
| | Acrea. | Acrea. | Acrea. |
| Sugarcane ... | 2,739 | 6,652 | 9,415 |
| Indigo ... | 13,171 | 51,835 | 56,720 |
| Cotton ... | 1,220 | 250 | 80 |
| Others ... | 11,587 | 7,770 | 8,585 |
| Total ... | 28,717 | 66,527 | 74,800 |

This clearly shows that the tendency is for sugarcane and indigo to increase. Cotton apparently is unable to obtain a footing.

There is a slight falling off on the Agra Canal, the decrease being about equal to that in cotton alone. There is, however, an increase in sugarcane, but almost the same decrease in indigo.

On the Rohilkhund Canals there is a rise in sugarcane and a falling off in rice, and, on the whole, there is a slight decrease. This is due to there being no demand for water for late kharif rice sowings.

On the Eastern Jumna Canal the increase is due to sugarcane.

5. Table III shows the assessment on account of occupier's rate of the last four years :—

TABLE III.

| | 1879-80. | 1880-81. | 1881-82. | 1882-83. |
|-------------------|-----------|-----------|-----------|-----------|
| | Rs. | Rs. | Rs. | Rs. |
| Upper Ganges ... | 12,01,470 | 9,09,785 | 9,69,853 | 11,01,834 |
| Lower Ganges ... | 31,072 | 4,15,906 | 4,92,948 | 5,11,824 |
| Agra ... | 69,478 | 98,035 | 1,69,898 | 1,57,621 |
| Eastern Jumna ... | 3,99,739 | 3,99,757 | 4,29,219 | 4,55,995 |
| Rohilkhund ... | 20,108 | 46,857 | 83,627 | 32,800 |
| Doon ... | 19,219 | 17,115 | 15,752 | 16,839 |
| Bijnour ... | 1,148 | 4,781 | 5,878 | 3,019 |
| Bundelkhund ... | 469 | 479 | 131 | 116 |
| Total ... | 17,42,699 | 18,92,733 | 21,15,706 | 22,80,290 |

The rate per acre is Rs. 3.08, and is therefore better than that of last year, which was slightly under Rs. 3. This is due to the increase in the better class of crops, notably sugarcane.

AL CULTIVATION.

(Communicated.)

[In the following communication, which is from a native agriculturist, we have made no attempt to change the English of the writer.—Ed., L. A.]

THIS crop is grown in almost all mallas of Berar. It is not heard that it is ever been made in the Deccan.

Uses.

It is known as a root-crop. It also produces seed-grain just like that of mustard, with the only difference of its colour. All seed is of the black colour. Oil of good medicinal character can be pressed from it, but no experiment has as yet been made to the effect. Roots of al make a deep red and rose colour. These roots are generally exported to England whence we get beautifully coloured stuffs of different sorts. These stuffs are sold very dear here. Whatever colour made from the roots is very deep. At some places in Berar, Klichpore, Khamgam, Daryapore, &c., some traces of its colour manufacturing are still seen. A greater portion of these roots is also exported from Berar to Chatterpore in Bengal where good mantles (rajayas), kharwas (red cloths used for making coverings to cushions) are dyed from its colours. These cloths are well known here as "Nagpore kharwas." The slenderer roots, the better they are considered for making colours. These roots when large are called "kandas." The slender roots fetch a double price in bazaar. It is a matter of the greatest importance in its cultivation that it should not be allowed to feed larger.

CLIMATE.

As this crop is well-grown in Berar, it must be said that the Berar climate suits far better to it. The climate of Berar is, in general, hot. The average of rainfall here every year is little more than 30 inches. There is a very little difference, if it ever is, between the Berar and the Deccan climate excepting some districts. Much rain is considered detrimental to this crop. In the first year a inferior dual crop, either of jwari or castor-plant, is generally made with the al.

SOIL.

The agriculturists here prefer for the crop the loamy sand of the calcareous order; deep black soil does not suit it at all, for it assists the natural propensity of its roots to penetrate deep in the soil, and thus to cherish large kandas to uselessness.

PLOWINGING.

The soil to be grown with this crop is not required to be ploughed. Such is the opinion of the cultivators of long standing. They say that ploughing makes the soil easy of penetration by the roots; and this very fact reduces the value and usefulness of the produce; second, if its roots are once penetrated deep, the soil cannot be cleared of them entirely. The remainders do great harm to any other crop made on the soil to the considerable loss of the owner. These facts, say the Berar agriculturists, induce them to prepare fields by making use of "buckhars" only. With this they turn up the soil. Its action is confined only to the surface soil. After turning the soil up and down a little, they sow the seed by a drill in closer lines. It is generally sown after the Mrig-showers watered the fields. A bigha requires about four payalis (kacha seers) of seed. If jwari is the object of growing with it, every payal (4 kacha seers) should be mixed with one seer of jwari. About ten days after, germs are seen peeping modestly on the field. The field should be weeded no sooner does the crop reaches the height of an inch. The work of weeding is generally done either by manual labour, or by an instrument. It requires three years to be ripe. The first year's expenses are defrayed on the income of the jwari sown with it. The second year gives a good crop of its seed which is quite sufficient to bear that year's expense on the field. During the third year the root crop is ready. The seed is sold in bazaar here at Rs. 20 to 40 per khandi (80 kacha maunds).

PREPARATION OF ITS SEED.

The trees bear fruits during the second year. The fruits are very hard. The shells of the fruits are filled up with small black grains. Having picked up the fruits from the trees, they are rotten being mixed with double the quantity of dung. While the fruits are being putrified, they are trodden either by men or by buffaloes. They are putrified to such an extent that the scene becomes very detestable. The pile itself becomes a lovely abode of dirty worms and insects. (This must be done at great distance from the habited locality to avoid nuisance.) This filth is taken after a fortnight to a river, where the fruits are washed clear, and broken too. The small grain are obtained from them. The ash of the husk of the fruits is very useful, as they say, to rub the teeth with.

No manure is required, or at least they do not use it for this crop. At the end of the third year the roots are dug to the depth of 4 to 5 feet. These roots are dug at the rate

of 2 lbs per acre. A male person digs about 5 acres a day. The income per bigha is roughly estimated to be from 3 to 84 kacha khandia. In bazar a khandi fetches from 40 to 60 rupees to the seller.

S. C. G.

Amruti, 1st April 1888.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The usual Monthly Meeting of this Society was held on Wednesday, the 21st March 1888.

W. H. Cossyall, Esq., President, in the Chair.

The proceedings of the annual general meeting were read and confirmed.

The following were elected members:—Moonahes Madho Lal, Majors E. C. Corbryn and F. R. Lewis, R.A., Miss De Momet, Messrs. D. M. Morrison, R. E. Waller, D. J. Zehlin, and H. J. Joakim.

Mr. C. A. White, Assistant Engineer, P. W. D., Hazaribagh, was proposed as a member by the secretary, seconded by Mr. J. E. MacLachlan.

CONTRIBUTIONS.

1. Administration of Bengal, 1881-82, and Report on its external trade for 1881-82.—From the Government of Bengal.
 2. Report on the Government Botanical Gardens of Saharanpore and Mussoorie.—From the Superintendent.
 3. Monthly meetings of the Agricultural and Horticultural Society of Madras for December 1887, and January and February 1888.—From the Society.
 4. Report of the Queensland Acclimatization Society for 1880 and 1881.—From the Society.
 5. The Indian Forester, Parts 3 and 4 of Vol. VIII, Nos. 1, 2 and 3 of Vol. IX.—From the Editor.
 6. Tropical Agriculturist for January and February 1888.—From the Editor.
 7. Report on New Gardens for 1881.—From the Director.
 8. Journal of the Asiatic Society of Bengal, Part I, Nos. 3 and 4, Part II, Nos. 2, 3 and 4 for 1882, and Proceedings for December 1882.—From the Society.
 9. Memoirs of the Geological Survey of India, Vol. XIX, Part 3, and of Palaeontologia Indica, Ser. XIV, Vols. 1-3.—From the Superintendent.
 10. Report of Chamber of Commerce for half-year ended 31st October 1882.—From the Secretary.
 11. Calcutta Exhibition of Indian Art Manufactures, 1882.—From the Committee.
 12. Journal of the Bombay Branch, R. A. Society, No 11, Vol. XV.—From the Society.
 13. Four kinds of Palm Seeds.—From the Director, Royal Botanic Garden, Mauritius.
 14. A quantity of cuttings of the Aloe Bokhara and vines.—From Superintendent, Botanic Garden, Saharanpore.
 15. A quantity of Pean Seeds.—From Mr. John Stalkart.
- The President having announced a valuable donation to the garden from Mr. W. Stalkart, of two fine large plants of *Avicaria Opail*, the best thanks of the Society were voted to that gentleman for this acceptable contribution. They have been planted out near the principal entrance gate.

APRICOT OIL.

Captain. Banon, 30th Native Infantry, submits a specimen of oil extracted from the kernel of the apricot of the north of India, and requests an opinion as to quality and value.

Messrs. R. Scott Thomson report on this specimen: "Is a good, pure oil, and may be used for all the purposes for which ordinary almond oil is at present employed. We have tested it to 10° Fahrenheit, at which point it does not congeal, which would make it suitable for lubricating fine mechanical works. There would be scarcely any demand for it in this country, but no doubt if it could be landed in England at 9d. per lb, it would meet ready sale. The actual value of it as an article of commerce can only be ascertained by sending a trial shipment of it to England."

GARO HILLS COTTON.

Read a letter from the Under-Secretary to the Government of India, Agricultural Department, requesting to be informed if the Society can furnish any further information regarding cotton from Chittagong and the Garo Hills. The secretary mentioned that all the information possessed by the Society had been introduced in the proceedings of last year.

The following is a note now furnished by the Government in continuation of the subject:—

The Revenue and Agricultural Department received lately from the Chief Commissioner of Assam, sample of a class of cotton which is grown in the Garo and Chittagong Hill Tracts. Quantities of the staple were sent for opinion to the Empress Mills at Nagpore, to the Elgin Mills, Milk Mills, and Woollen Mills at Cawnpore, to the Saxon Woollen Mills at Umritsur, to the Indian Carpet Manufacturing Company at Allahabad, and to the Agricultural Society of Calcutta.

The opinions received are unanimous in declaring the cotton unsuitable for spinning purposes by itself, because of the shortness of the fibres and their hard, unpliant nature, which gives them the tendency to separate themselves from each other instead of uniting together on twisting twist. The staple is said to resemble in almost all respects the Nagpore *herry*, or what is in the Berars called *belati* cotton; but it seems to be more regular in

length and slightly stronger. The introduction of seed of this cotton into the Central Provinces is deprecated by the Manager of the Empress Mills, who some time ago also brought objections against the Nagpore *herry*.

The cotton does not, however, seem to be altogether useless. It is valued, and highly so, for mixing with certain classes of wools, from its hard, harsh, and crisp fibre; and in fact is said in some respects to more resemble wool than cotton. For carpet-making, too, the Indian Carpet Manufacturing Company of Allahabad approves of it, and asserts that it is a superior commodity, and would be valuable for the finer kinds of stair and carpet cloths. The cotton has already attracted attention in commercial quarters, and an export trade has sprung up. The Deputy Commissioner of the Garo Hills District (Captain R. St. P. Maxwell) reports that, roughly, the amount of cotton exported, annually from that district is not less than 40,000 maunds when cleaned. The official returns of trade on the other hand show that 35,300 maunds of cotton are exported from Chittagong via Naraingunge. The Agricultural Society reports that the staple is already being extensively used in the manufacture of Saxon woollen fabrics on the continent of Europe.

The wholesale price of the cotton in the Garo Hills district varies from Rs. 10 to Rs. 17 a maund according to the season of export and trade demand. The price in Calcutta varies between Rs. 18 and Rs. 19 a maund.

Waste land is very abundant in the Garo and Chittagong Hills districts, and Captain Maxwell reports—referring to his figure of export (40,000 maunds)—that treble that quantity of cotton could be grown by the Garos if a ready market was available.

A few years ago an attempt was made to induce the hillmen to remove the seed prior to packing the cotton for sale, and for this purpose a large number of simple machinery were imported from Calcutta and distributed among them, but the movement met with no success. Captain Maxwell, who mentions the fact, explains—

"I have noticed, however, that a Garo is susceptible to improvement when the change carries with it a pecuniary advantage; and I have no doubt that if the value of cleaned cotton at the local markets makes it worth while for the Garo grower to produce it in this state, he will do so. The lack of enterprise is not so much with the Garo as with the first purchaser of the plains, who generally is too apathetic and indolent to enter into a vigorous trade."

He adds:—"If an inducement is held out to export the cotton from these hills in a cleaned state, I will take every measure to see that the advantages to be thus obtained are carefully made known to the interested parties."

A demand seems to exist in Australia for just this sort of cotton for mixing purposes. A sample of it, sent by the Revenue and Agricultural Department to a firm in Melbourne, was reported on by it "as splendidly suited to their purpose 'if cleanliness is kept up to sample.'" The first cost, however, was considered rather high, for, to the price then ruling, viz., Rs. 10 per bazaar maund in Calcutta, was to be added rate of freight to Melbourne.

More recently a fall in price occurred; and the firm availed themselves of the opportunity to send an order to Chittagong for a small trial consignment. The result is not known yet.

AMERICAN SUMACH.

Read the following letter from Colonel J. Stewart, R.A., Superintendent, Harness and Saddlery Factory, Cawnpore, in reference to the Divi-Divi:—

Having seen in the proceedings of your Society, published in the *Pioneer* of the 15th instant, a mention of American Sumach or Divi-Divi (*Oxalypintia coriaria*) as a useful plant for tanning leather, I beg to inform you that I have successfully reared the plant for the last 20 years in Cawnpore, where the grounds of the factory of which I have charge are covered with plantations of it.

I originally got the seed in 1862, from Bangalore, where the officers of the Madras Artillery had plantations of it for use in their regimental tannery. Subsequently more seed was procured from the Botanical Gardens at Calcutta, and the plant has thriven very well here, though the seedlings require great care and cultivation for the first few years.

The frost of the cold weather in these Provinces is injurious to the young seedlings, and protection is required for them. Field rats are great enemies to the growth of the plant.

I have distributed seeds from Cawnpore to several applicants for them, and am prepared to distribute more if required.

The secretary intimated that he had requested from Colonel Stewart as full information as he could kindly afford of the ages of his trees, the quantity of pods obtainable from each, and the weight required for tanning leathers of certain kinds in comparison with native tans, &c. He had also applied for seed to meet a probable steady demand, now that the value of the divi-divi was becoming more generally known.

In connection with the above, a note was introduced from Mr. S. S. Jones, C.S., Divisional Officer, Deoghur, sending a few particulars from the Forest Officer of the Sonthal Pergunnahs. Mr. Jones has likewise promised a quantity of seed.

Also an application from the Executive Engineer of the Brahmini Division, Cuttack, for seed of divi-divi for trial on the canal banks. (Compiled with.)

JAPAN PEA.

The Secretary submitted the following note from Captain Fegson in respect to the Japan pea sent to him (and to some other correspondents) in the early part of last year:—

The seeds of Japan pea received by me in February 1882, were partly distributed to several gentlemen at this station (Dahra). The seeds germinated, and I was subsequently informed that all

the plants died off during the hot weather. At Mussoorie some seeds of this pea, sown in a friend's garden, germinated, grew to the height of two feet, flowered, and bore two pea-pods at the joints of each twig. These pods were just like the pods of the *urhar dal* (*Cajanus sativa*), the leaves were very like those of the *moh dal*, only round at the end instead of pointed.

I suspect the Japan pea seed sent to the Society was not the variety so highly spoken of in America. I enclose a photo. of the Japan pea as produced in Mr. Gregory's seed farm, and think it would be a good plan for you to send him the photo, and ask to be supplied with the seed of that particular Japan pea. In the *Indian Agriculturist* for December 1882, pages 464-55, there is a very interesting paper on the subject of this pea, of which it seems there are four kinds, viz. "the yellow, brown, round black, and long black." The pea sent me is of the usual pea colour, which makes five varieties.

It would be advisable to obtain some of each kind to be packed in tin before shipment.

Information as to time of sowing in Japan should be asked for. As regards seed from Mr. Gregory, if despatched so as to reach Calcutta in August, they would be in growers' hands to sow as soon as the rains ceased, which would be by the 10th to 15th of September.

I came down from Mussoorie on the 26th October, and in November made two sowings of Japan pea seed, putting three seeds in each dibble, but as the seed rotted, it was clear that germinating powers had been destroyed. I kept the seed in a well corked bottle locked in a box, so no damp could have got to them. November was a very warm month, and as all common pea seed came up, the failure of the Japan pea could only be due to death of seed.

I think the pea answered at Simla, but have not heard.

JAPAN SINGLE-BULLOCK PLOUGH AND DRY RICE.

Captain Pogson sends the following notice regarding the above plough and Japan dry rice:—

It appears that the Japanese possess a plough which is worked by a single bullock. It would be, I think, advisable to secure one of these ploughs as a model, as I think with suitable alteration such a plough would suit for camel ploughing—four camels can draw a 9-pounder brass cannon and limber, with a mounted man per camel; one camel easily draws a park phaeton up hill from Kalka to Solun on the Simla road, at a trot; then why should not one camel draw a Japan single-bullock plough, made on an enlarged scale, just as well as two bullocks do the common Indian plough?

In Japan two varieties of rice are cultivated—"wet rice," on the low lands under irrigation, and "dry rice," on high lands and mountain or hill slopes, without any irrigation whatever.

If this dry rice suited the Monghyr, Rajmehal, and Deerbhoom hills, the result would be most beneficial, and greatly increase the rice-supply of the country. This rice was brought to notice by a British Consul at Japan, but I cannot lay my hands on the paper; anyhow no difficulty exists as to securing a supply of seed rice of this variety. But it should be packed in tin, otherwise the sea air will kill the seeds. I am pretty certain that the dry rice of Japan would suit the Himalayas north of Umballa, and so on to Kangra, which already produces very large quantities of wet rice. It would be sound policy to introduce this dry rice into such parts of the Afghan frontier where wet rice is now cultivated. The Government of India might, if asked, help in this matter. (Referred to Government of India.)

MEXICAN ALOE FIBRE EXTRACTOR.

Read a letter from the Under-Secretary to the Government of India, Agricultural Department, returning the model of the Mexican aloe fibre extractor,—see proceedings of November and January last,—and forwarding a working machine four-fifths of the size.

Mr. T. F. Peppe, of Arrah, in allusion to the above machine, writes as follows:—

"I am anxious to know something of the machine for cleaning *Agave* fibre, which I understand is now in Calcutta, and want to know what it costs, and if it does the work required thoroughly or only partially. I have been experimenting in the matter of fibres in connection with a tea estate, and have therefore seen that a machine, such as they use at the Mauritius, is urgently required both for *Agave* and *Fourcroya* fibres. I saw samples of the latter fibre at home valued at £45 per ton, and as the plant flourishes in Chota Nagpore, I do not see why it cannot be produced on a large scale. If you can assist me in regard to the preparation of *Agave* for *Fourcroya* fibre I will be much obliged."

The secretary mentioned that he had informed Mr. Peppe that the above machine was available for another to be made from it, and that he might obtain some useful practical information on the subject generally from the Superintendent of the Hazaribagh jail.

COMMUNICATIONS ON VARIOUS SUBJECTS.

The following papers were also submitted:—

1. From C. F. Manson, Esq., Dooanka,—a paper on the mohwa, its useful properties, &c.—(Transferred for Journal.)
2. From the Under-Secretary, Government of Bengal,—a Note on Wheat Mildew.—(Transferred for Journal.)
3. From E. H. Man, Esq., Port Blair, intimating, in reply to enquiry, that the quantity of tea seed forwarded in the cold season of 1882, through the Society's agency, has germinated well, and the young plants are all healthy and progressing satisfactorily.
4. From W. Lee, Esq., Ranghur Tea Garden, rd Naini Tal, reporting the failure of the Japan potatoes presented by Mr. H. A. Firth.—(See meeting of April 1881.)

5. From the Executive Engineer, Brahmini and Byturni Division, Cuttack, applying for a quantity of nms of *Arceuthobium*, with full instructions as to cultivation, probable yield, &c. (Seed partially supplied and information given. More seed to be supplied next season.)

6. From Under-Secretary to the Government of India—forwards copy of a letter from the British Consul at Manila, respecting model of a Manila hemp extractor. With regard to hemp extractors, writes Mr. Wilkinson: "I found, on enquiry, that none can be had here, and the province of Manila itself produces no hemp; but I have written to Albay, which is the centre of a large hemp district, in order to obtain the required model, which, if sent to me, I will at once forward to the Agricultural and Horticultural Society as desired."

SELECTIONS.

FIRE CONSERVANCY IN INDIAN FORESTS.

THE heavy expenditure annually incurred by the Forest Department under the head of fire conservancy, and the partial success that has attended its efforts to control jungle fires, induces me to invite attention to the matter, and inquire whether the benefit the forests have derived since this branch of forestry has been organized compensates for the enormous expenditure incurred thereon?

Forest fires, beyond doubt, may claim the same antiquity as the forests they now overrun. If, therefore, they are so destructive to seed life, and such a hindrance to the perpetuation of forests, as has been alleged, it seems worth while making an effort to account for the jungles in India containing such magnificent timber trees when the British took possession of the country, and to explain how it is they have continued to meet the heavy demand made on them since that period. I confess my inability to find a solution to this apparent anomaly, though it is possible there may be others, who are in favour of fire conservancy, who will clear up the difficulty, and explain what I am at a loss to understand. What I desire to know is, whether indisputable facts exist which tend to prove the destructive nature of jungle fires, or whether the consuming nature of this element has been made the excuse for failures in arboriculture that could not otherwise have been satisfactorily accounted for, and Government thereby induced to sanction an elaborate system of fire conservancy at any cost?

My experience in the matter makes me sceptical, and tends to the belief that jungle fires are not as destructive to forests in India as they are said to be. Indeed, I would venture even a step further, and ask whether it is not possible that these annual conflagrations are not calculated to do more good than harm, by opening out the soil, consuming rank vegetation (that renders a forest life so deadly), destroying insects, checking the too rapid increase of the wild beasts, and admitting a free circulation of air? The finest timber, beyond question, is to be found where trees are not crowded, where there is a free circulation of air, and where blight is not apparent; and it is only in forests (in India) through which fires annually travel that such conditions prevail. Nature has a mysterious way of fulfilling her various duties, and it yet remains to be proved whether she has not in the present instance sought the services of Hephaestus to bring about a series of conditions essential to plant life.

After a forest has been fired, the ground presents a net-work of cracks, varying in width and depth. These fissures, on the first burst of the monsoon, admit of water, air, and other gases, coming in contact with the roots of the plants, and serve to destroy unhealthy acidity in the soil, and to promote the decomposition of vegetable matter.

Soils, like plants, are composed of organic as well as inorganic matter. The organic part of soils is chiefly derived from the remains of vegetable and animal substances. This organic matter, by the action of alkaline substances, is resolved into ulmic and humic acids. As the vegetable matter decays, this organic portion of the soil also gives to the land the various inorganic substances found in its ashes.

The inorganic part of soils consists in general of saline soluble substances, and of certain earthy insoluble substances. From these soluble compounds the plant obtains nearly all the saline matter contained in its ash. The rain dissolves these saline substances, but in dry weather they re-ascend to the surface, and are thus brought in contact with the roots of growing plants.

The surface soil of tropical forests during the rainless months is known to be dry and indurate. It stands to reason, therefore, that when the land is not loosened either by artificial means, or opened out by the agency of fire, much of the organic matter or humus is washed away (especially in the case of teak trees which affect hill-sides), or takes a longer time to reach the sponginess of the trees than would be the case had the land on which they grow been opened out by whatever means. Apart, therefore, from the fact that forests, whose surface is not broken up, are robbed of much nutritious matter, the trees in a measure lose the full benefit of the early rains, and remain dormant for a longer period than would be the case had moisture permeated to their roots at the first burst of the monsoon. Thus far I have endeavoured to give my reasons for supposing that jungle fires act beneficially by opening out the soil to the free and early action of water, air, and other gases.

From a sanitary point of view, I presume none will gainsay the benefit jungle fires bring about, by consuming the rank vegetation that alike poisons the air and water in localities where forest officers spend the best part of the year, and from the effects of which

many valuable lives have been sacrificed. I learn from the resolution on forest administration in British Burmah for 1880-81, that of the superior staff, comprising seventeen officers, seven suffered from jungle fever, one died, and one, after a prolonged and severe illness, had to leave the province. This return bears unfavourable comparison with that of previous years, and tends to the belief that the unhealthy condition of the department is increasing in ratio to the progress made in fire conservancy.

Beyond doubt jungle fires slay blight, and destroy insects pernicious to trees; but whether the good they effect in this respect compensates for the damage they are supposed to do, is a matter for serious consideration. I have seen extensive plantations of teak, hiker, and alsoo utterly ruined by small black hairy caterpillars that feed on the buds; and have also seen plantations of the same trees unscathed by jungle fires that have been rapid in their course, a circumstance borne out by the following extract from the resolution on the forest report of British Burmah for 1880-81:—"In the Pegu circle the protection from fire of eighteen reserves and plantations was attempted. Fire occurred in ten of these. In some cases the fire was very trifling, but in several instances there were serious conflagrations. It is, however, satisfactory to find from later reports, submitted after examination of the principal reserves which suffered, that the damage done is not serious. In the Mokeka-Beilin reserve none of the trees appear to have been killed. In the Bewet reserve the actual damage has not been found to be so great as was at one time feared, although a good many of the teak plants have perished."

Now, in respect to the loss of life from wild beasts, forest reports are silent; it is difficult, therefore, to arrive at any satisfactory conclusion regarding the part jungle fires play in suppressing their perpetuation or increase. It is on record, however, that within the last two years 246 men have been carried off by tigers in the Sunderbans Forests division, an area that comprises the wooded portion of the gangetic delta, where, as a matter of course, jungle fires never occur, and tigers abound. All who have indulged in the delights of tiger-shooting know it is hopeless to expect shikar in jungles recently burnt over, and naturally wend their way to those forests in which fire has been best controlled. In 1881 the largest number of tigers killed in the Madras presidency was in the Malabar district, where fire conservancy does not exist.

I have now illustrated how it is possible that jungle fires may be more beneficial than injurious to forests, and must leave it to those who are in favour of fire conservancy to correct my views where they are at variance with existing facts. Controversy unquestionably is the best means of developing truth, and all I desire is to arrive at the real truth of the question at issue.

From 1876-77 to 1880-81 over 1,00,000 rupees have been expended on fire conservancy in British Burmah and the Central Provinces, and, according to recent resolutions of the Government of India, it would appear that the whole area protected from fire in these provinces during that period must be retraversed by fires once every eight and nine years respectively. At the present rate the annual conflagrations are encroaching on the areas protected. With such startling facts on record, it seems high time that the pros and cons of fire conservancy should be most carefully considered, and a more economical and efficacious system introduced if possible.

Referring to fire conservancy in Burmah during the year 1880-81 the Chief Commissioner writes:—"The business of protecting reserves from fire forms a very difficult problem in Burmah. This year we have spent 10,000 rupees in attempting to protect from fire 98,000 acres, out of a total of 1,300,000 acres of reserved forests; yet fires occurred once, and more than once, in sixteen reserves out of twenty-eight to which our efforts were directed. The reserves will probably aggregate 2,500,300 acres before the demarcation work now in contemplation is finished. At the present rate of charge the fire protection of this great area would cost over two and a half lakhs of rupees. Even then we could not hope to keep out fire in years of rainless spring and summer months, or from forests where bamboos had flowered over large areas. It is comforting to find that teak of good growth seems to escape almost unscathed from ordinary fires, and that even teak plantations, on toungyas or elsewhere, have suffered much less from fire passing over them than would have been expected. Though this is so, nevertheless the work of protecting from fire a yearly-increasing area of reserves and plantations must be maintained as one of the primary objects of forest conservancy in Burmah." Here, again, we have striking proof of jungle fires not being as destructive to forests or plantations as one is led to suppose from the amount that is yearly expended on their suppression and control. However this may be, certainly I concur with Government in condemning the present system of annually increasing the area protected from fire before that first attempted has been rendered comparatively fire-proof. The resolution explains "that fire protection, in order to be of real value, must be continuous, and that, before further extensions were attempted, it was necessary to make sure that the forests previously taken in hand were quite safe."

No further extension of fire protection should ordinarily be taken in hand until the existing areas under protection are made quite safe. When this has been accomplished and new areas are brought under protection, they should be shown separately, so that it may be possible to trace the results, in the case of each block, from the time when protection commenced in it. The only effect of increasing the area attempted is to diminish the apparent amount of failure without doing any good."

Now, in respect to teak, and bearing in mind that this tree is not gregarious in its habit, but grows amongst trees of comparatively no value, it occurs to me that a considerable saving might be effected, and better results obtained, were fire conservancy confined to areas where teak seedlings grow most abundantly, and that when the seedlings have attained a sufficient growth to be beyond the influence of fire, a new plot be taken in hand, and so

on. If the areas now protected from fire were carefully examined, I am satisfied that nearly fifty per cent of the land would be found occupied by trees or scrub jungle comparatively valueless, and that consequently a far larger amount is expended on fire conservancy than there is any necessity for.

Subsequent to the completion of this paper, I have seen the "Progress Report of Forest Administration in the Hyderabad assigned Districts" for 1881-82. Corroborative of my views regarding the evils that arise from fire conservancy, the Conservator writes:—"Hitherto the beneficial effects of fire conservancy, such as the creation of a forest soil, increased reproduction, diminution in the rank growth of grass, &c., have annually been recorded, but I now have to bring to notice an evil which is making itself felt more and more every year, viz., the enormous increase in insects, some troublesome only to man and animals, other injurious to vegetation. Among the latter may be mentioned a caterpillar which in the first break in the rains, especially if it is a long one, attacks the teak tree in swarms, leaving it almost bare of foliage, and thus checking its growth to a serious extent. Teak seedlings, too, suffer great injury from an insect which buries its eggs in the latest growth. On the production of the larvae large excrescences are raised, and the leading shoots ultimately killed. How far this insect will effect the future of the trees remains still to be seen. The 'borer,' too, is becoming much more plentiful than formerly." I differ, however, from the opinion expressed in respect to fire conservancy being beneficial to forest soil, for I hold the reverse to be the case.—S.—*The Journal of Forestry.*

FOREST PROGRESS REPORT FOR BRITISH BURMAH 1881-82.

THE report before us shows how very successful Forest Administration has been in British Burmah during 1881-82, and how vast are the timber resources of that rich province.

Demarcation work is still in progress, and the total area of the reserve forests was 3,274 square miles, or somewhat less than that of the reserves in the North-Western Provinces. It would be interesting if the proportion of the reserved forest area to the total area of the province were always given in Annual Reports.

Eight hundred and thirty-six square miles were added during the year, (most of the new reserves containing more or less teak-producing land except the Mindone Yowa in the Prome Division.)

Reservation in Burmah interferes very little with the privileges of the people, because the very large forest area left outside the reserves more than suffices for all their present wants. The wild uncivilised Karen, never accustomed to restraint of any kind, naturally objects to forest reservation, and the Pegu Conservator very graphically explains his view. He says:—"The Karens themselves say that once they were like jungle-fowl, hiding where they liked, scratching the earth here and there and putting in a grain of rice and eating what came of it, if the *nats* (i.e., spirits), permitted, but that now the Forest Department put them into boundaries here and boundaries there, and they feel like pigs in a pen. But after a certain time they rarely deny that their latter state is preferable to their former, more especially in or near fire-traced reserves, where work is constantly obtainable."

Forest reservation will, we may be sure, have a great civilising effect on these interesting people, they will learn to settle down in the neighbourhood of forests where labor is constantly required, and by more frequent contact with Europeans and civilised Burmans will become useful, instead of destructive, members of the community.

In the reserves there are very few rights, and those that do exist, such as the use of bamboos for home consumption and grazing rights, will not be detrimental to the future of the forests.

The fact that the export line of the two new reserves in the Toungthoo Division lies through Upper Burmah, shows what a defective frontier we have there, and that some rectification is required.

Fire protection has been extremely successful, and in spite of the great difficulties which have to be overcome, will compare favourably with that in any of the other provinces under the Government of India, as only 1.6 per cent of the protected area was burnt.

Inocuidism is common, and several fires occurred from this cause. One of these happened at the Magayee Plantation, and the Extra Assistant Commissioner decided that it was the fault of some forest subordinates, without taking the trouble to examine three eye-witnesses. This is an evil which it is impossible for Forest officers to check, unless they receive every assistance from the Civil authorities.

Mr. Ribbentrop gives an interesting account of the consequences of frequent fires. He says:—"The first consequence of these constantly recurring fires are bamboo forests with standard trees in the hills, and Kaling grass savannahs in the plains. The cover of head leaves on the ground is annually consumed, and no humus is formed."

"The rain-storing power of the forest is lost, and the bare friable soil is washed down into the streams. Wherever a small flat stone, a piece of wood, or some other obstacle protects the ground, this forms after the rains the roof of a little mud pillar, and the soil round it having been washed away and carried down by the streams, is doubtlessly one of the main causes of their rapid silting up. This erosion does not take place in areas which have been successfully fire-protected for some years, and the streams in fire-protected forests become more and more perennial."

The plan by which Karens and other forest people protect the forest areas near their own settlements is excellent, and will doubtless be extended, seeing that the cost of protection in this way is a quarter of that by any other method.

Eight hundred and seventy-two acres of plantations were made during the year, and principally consist of new teak *toungyas*, containing over 800 seedlings per acre. It is hoped this system will be extended until Mr. Brandis's programme of 2,000 acres per year is carried out.

Four hundred and fifty acres covered by flowering bamboos (*Secooides* not mentioned) were burnt, and planted up with teak seedlings on the *toungya* system, 500 acres being burnt for further operations. As the Chief Commissioner remarks, the system is an excellent one, especially as it can be seen the season before, by the bamboos not sending out new shoots that they will flower next year.

The reproduction of Cutch has been tried with success in the Tharawaddy Division, and an attempt will probably be made to create large Cutch *toungya* plantations in the Thayetmyo District.

Experimental cultivation of various exotics has been continued on a small scale with varying success. The experiments are generally carried on in a half-hearted way, and success is imperilled by unwise economy in cutting down expenditure on weeding, fencing, watering, &c.

Mahogany would do well if it were not for the attacks of insects, probably the larva of a beetle. It is stated that "some trees have their terminal shoots eaten off, while others are attacked just above the collar and simply girdled, others again are bored along the whole length of their stem." This liability to injury of introduced species is very curious, and has caused a great havoc amongst Australian trees at the Cape.

Tea and coffee grow at Thandaw, and it is hoped that private capital may be attracted to the locality as soon as the railway to Tounghoo is opened.

Broussonetia papyrifera appears to be as much at home in Burmah as it is in the Himalayas, and there is a thriving little plantation in Tharawaddy.

The Vanilla orchid will probably be successfully cultivated at Magayee, where a vanillary has been built, and where two-year-old plants have fruited.

Over 24,000 trees were girdled, including nearly 19,000 teak, all save 200 trees being in the non-demarcated area, where it is calculated that 40,000 marketable teak remain, and then work will be commenced in the reserves.

Foresters in the older provinces will read the part of this report dealing with the yield of the forests with unmixed feelings of envy. Revenue was collected on 76,000 tons, or 3,800,000 cubic feet, and free permits were given for over 42,000 tons of timber, according to the review by the Government of India, although it is not understood how the latter figure is arrived at, seeing that free permits are given for trees without specifying dimensions, these trees being all cut outside reserves and not marked in any way.

This large yield, it must be recollected, only shows the outturn of teak 31,000 tons, and the 16 other reserved kinds 87,000 tons, and is exclusive of all the other numerous species of timber, many of which, such as Mango, Tonkkyan (*Terminalia tomentosa*), Yone (*Anogeisus acuminata*), Petwoon (*Berrya ammonilla*), are regarded as valuable trees in other parts of India. No free permits are required for cutting any trees save the reserved kinds outside the demarcated area, and nearly 30,000 logs of 72 different kinds passed through the revenue stations of the Rangoon Division alone in this way free of duty.

One lakh thirty thousand tons (6½ million cubic feet) of teak, valued at over 100 lakhs of rupees, were exported from Rangoon and Moulmein, this including of course a large quantity of timber from Upper Burmah. Of this timber, England took 50,000 and India 80,000 tons, the exports to other countries being insignificant.

The rates realised were high, being in Rangoon on an average Rs. 66 per ton for first class, and Rs. 42 for second class timber, and at home varying from £13 to £15 per ton.

As a proof of how little the Forest Conservancy in Burmah presses on the wants of the people, the revenue derived from minor produce was only Rs. 8,000; if we exclude the revenue on Cutch, Rs. 48,000. Grazing and fodder grass realised the small sum of Rs. 132.

Four-and-a-half million bamboos and ten million palm leaves for thatching passed through the Rangoon revenue stations free of duty.

Rs. 57-8-0 were received on 11½ million cheroot leaves (from *Cordia myxa*) in the Tharawaddy Division.

Wood-oil is chiefly extracted from Kanyin (*Dipterocarpus laevis*), one man tapping from 30 to 40 trees in the season, from which he extracts 150 to 200 lb of oil, sufficient to manufacture 2,000 to 3,000 torches, which sell locally at Rs. 1-8-0 per hundred.

Although only Rs. 56,000 were credited as revenue from minor produce, the value of exports from Rangoon and Moulmein exceeded 36 lakhs of rupees, the articles exported consisting of gums and resins, cutch and gambier, stick-lac and wood-oil.

Thirteen lakhs of produce were sent to the United Kingdom, and over 9 lakhs found a market in India.

The financial results of the year are very satisfactory, and the surplus of nearly 11 lakhs of rupees exceeds the total receipts of many other provinces.

The surplus, however, is an exceptionally large one, and is due to a rise in the price of teak, and in consequence a larger out-turn of that timber, as well as to the supply of sleepers, &c., for the new railway to Tounghoo. For this purpose, the Rangoon Division supplied 16,000 *Pyzkado* (*Xylia dolabriformis*) logs, and the

agency, Tounghoo and Shweyboon Division supplied over one lakh of sleepers, principally of *Pyzkado* (*Xylia dolabriformis*) and *Lala* (*Lagerstrœmia tomentosa*) with a few of *Teak* and *Dokeyan* (*Terminalia tomentosa*). These sleepers, and other timber supplied to the Rangoon and Irrawaddy Valley State Railway, a large portion which was cut within the reserves, gave a revenue of more than 8½ lakhs.

Excluding the 10 elephants attached to the Agency Division, there were 33 elephants belonging to the Department. Their feed cost Rs. 1,039, or the moderate sum of Rs. 3-10-0 per month. In the Rangoon, Western, and Shweyboon Divisions, the cost of the food of 13 elephants was nil, as forest labourers refused to maintain them in good condition, and no rice or paddy was given. The average cost of feed and keep, including gear, is not however less than Rs. 50 per animal per mensem.

Dynamite was successfully employed in many cases to remove rocky obstruction in timber-floating streams. One of Rangoon's stream tree-fellers has recently been procured from England, for use in the preparation of locomotive fuel, for the Irrawaddy State Railway, and we hope it will prove a good investment financially.

Mr. Ribbentrop, who has now left Burmah for his old province, the Punjab, has been warmly thanked by the Chief Commissioner for the excellent service he has done in the Burmese forests.

SUGARCANE CULTIVATION.

ABOUT two months ago, the Government of India, in the Agricultural Department, issued a rather interesting order on the sugar industry in India, the growth and cultivation of sugarcane, and the manufacture of sugar. The returns submitted at the time go to show that the industry has not fallen off, but that it has not made the progress it ought to have, and while in many other branches of industry there has been an advance, such as the cultivation of coffee and the growth and manufacture of tea, sugar has almost kept its old position. In dealing with the subject, the Government of India gave no special attention to sugar cultivation in this presidency. The subject was discussed more with reference to the North-West Provinces, Bombay, and Bengal, and Madras was quite forgotten. True it is that the Madras presidency has not taken a very prominent position in the growth of the cane and the manufacture of sugar; but there was a time, not very long past, when the production of sugar in the mofussil districts of this presidency received very great attention, and when European capital largely embarked in an enterprise which did not turn out as well as anticipated. It is said that the total annual production of sugar in this country is about 2,000,000 tons, besides the produce of palm trees, which yield about 150,000 tons. The total production of sugar is not equal to the demand, and hence it is that about 986,000 tons are annually imported from Mauritius and other sugar-producing centres. This large quantity is chiefly attracted to Bombay and Central India, while the Madras presidency contents itself with supplies from the northern districts and Bengal, where the trade is large, and where the manufacture of sugar, though not keeping pace with the progress made in other industries, has not declined.

In the Madras presidency the sugar manufactured at Auka, Bimlipatam, Chitavale, and other places, once commanded very good prices, and the manufacturers of the different descriptions of sugar being Europeans, merchants entered heart and soul into the enterprise, and hence the success that attended almost every endeavour to manufacture a really good article. For many years some of the leading mercantile firms in Madras had their factories on the coast ports, and at almost every successive season thousands of bags were shipped: gradually with steady improvement in the quality of sugar and the demand that existed in Europe, the sugar trade assumed large proportions, and shipments proved remunerative. But of recent years a change has come over the spirit of the enterprise, and while fine brown sugar was manufactured for shipment, the merchants are now content to ship jaggery—such as is chiefly consumed by the poorer classes, and hence the manufacture of sugar has been given up by many of the leading merchants who are content to deal with jaggery, or what is more technically called *clense*. The worst quality—the refuse of the market—was lately sent away from Madras in shiploads, and what likelihood is there that any decided change for the better will take place in the production and manufacture of sugar so long as exporters content themselves with the stuff sold in the market? But while this branch of export trade is not improving, the manufacture of sugar for local consumption has not declined. We have seen samples of Auka sugar that will bear competition with the best sugar manufactured in England and sent to India for sale; and from some of the Southern districts and from Mysore—especially from the Astragan district—the sugar manufactured is of excellent quality, and always finds a ready and remunerative market. Some years ago, a well-intentioned German missionary set up a sugar factory in the North Arcot district. He was engaged in mission work and with a view to teach the newly-made Christians an industry by which they may be able to obtain a livelihood, he successfully grew sugarcane, and turned out sugar of very superior quality. Allusion to the work carried out by this zealous labourer in the mission field is made in the North Arcot District Manual. But with his death the good work begun was not continued, and what would have turned out a profitable and paying industry has been allowed to gradually die out for want of encouragement and support.

The question may, however, be asked if in the Madras presidency there is room for the development of the sugar trade. The answer may safely be given in the affirmative. The manufacture of sugar must depend upon the production of the cane, and in effect

this cane, will naturally attract attention from growers. Sugar-cane is not as easily grown as horse gram or any other dry grain. A system of high cultivation must be pursued; and if it is, the results will fully compensate the outlay of time and money. In his report upon the capabilities and prospects of the Coimbatore district, Mr. Robertson, Superintendent of Government Farms, states that the facilities offered for sugarcane cultivation in that district are very great, but that only 8,000 acres of land are on the average planted with the cane, while under fair average conditions, a large part of the cultivable land of Coimbatore may be set apart for sugarcane which will bring in a return of from Rs. 80 to Rs. 100 an acre against crops that yield no more than Rs. 12 an acre. According to Mr. Robertson, "the Coimbatore district offers many facilities in its climate and soil for the production of sugar, and it is to be regretted that such a small area is cropped with the sugarcane." Lands specially set apart for the growth of the cane have steadily lost their producing capabilities, and where, about thirty years ago, the yield was more than 120 maunds per acre, it is now not quite fifty maunds. We need not go on quoting from Mr. Robertson's report to show that, in the mofussil districts of this presidency, the cultivation of remunerative crops is neglected, and that industries which may be worked to the greatest advantage, are allowed gradually to die out. What has been achieved in parts of the Bengal and North-West Provinces in the matter of sugar cultivation may be, with a little trouble and care, accomplished in our own presidency. The remedy is in the hands of the better classes of the ryots, and it is hoped that, with the diffusion of an improved system of agriculture, such as taught in the new School of Agriculture, this industry will extend, and bring with it increased advantages.

PLANTING AND CULTIVATING NORTHERN CANE.

By PROFESSOR W. A. HENRY.

THE old sorghum plant of war times is again a claimant for a portion of the farmer's field and attention. While in the early days the excitement caused by this plant subsided as rapidly as it arose, there are reasons which show to a certainty that this time sorghum has come to stay. The plant, in emerging from an obscurity of nearly a score of years, has taken the more popular title of "Amber Cane," and with the changed name come qualities that must as surely win for it friends, as the bad qualities of the old sorghum made for itself enemies wherever it was known. Some of our Western States have already grown amber cane in large quantities, and the satisfactory sales of the syrup warrant an increased acreage. To properly plant, cultivate, and manufacture, are all points not yet understood by our farmers, and for some years to come there will naturally be much discussion upon these topics. Let us consider at this time the planting and cultivation.

First of all, good, pure seed should be secured and carefully tested. Two pounds of seed are allowed for each acre. By count I found that one ounce of seed contains 1,730 grains. This gives 27,680 per pound. Good seed should be free from the hulls, and weigh not less than 58 pounds to the bushel.

No one should think of planting without testing the seed, to see whether or not it will grow. To accomplish this fill a small box or flower-pot nearly full of earth, lay on the earth a cotton cloth, and place on the cloth 100 seeds; over the seeds lay another cloth, and then put on a layer of earth an inch thick. Water heavily at first, and place in a warm place by the stove. With proper care, the seed should be ready to examine in six days. If the seed is good, not less than 90 of the grains should show sprouts. The seed test should be made so early that a second can be secured, if the first fails.

As to the use of manures on the land, I should say that no rank stable manure should be applied direct to the land. The less manure that can be used, the better for the quality of the syrup. In general, the land should be in good heart, but it need not be so rich as for a heavy crop of corn, unless naturally so. Manure darkens the syrup, as repeated tests show.

The question of manures brings us to a consideration of the soils best adapted to cane growing. Upon this point there is quite a uniformity of decision in favour of sandy soils. Most certainly this soil pays best for cane, in comparison with stronger land, when the relative yields of this and other crops are considered. Cane grown upon sandy soil furnishes the clearest juice, which in turn makes a syrup of the lightest colour and finest flavour. Often, however, dark soils and clays make fine syrups and afford large yields.

The preparation of the soil for planting is one of the points where many mistakes are made. The ground should be much more carefully prepared for cane than for Indian-corn. Indeed, no one should allow the seed to be brought into the field until the whole surface is as mellow as a garden. To get the soil into this condition requires not only that it be well ploughed, but that the roller and harrow be well employed. The last harrowing should take place on the day the seed is planted. To get the most syrup from a given area of land, plant in drills three and-a-half feet wide, five or six seeds every 18 inches. Many prefer to plant checks, as with corn, but less cane can be grown that way. If possible, plant with some kind of horse planter, which, if it does its work properly, cannot be equalled by hand-planting. With a Keystone one-horse planter, and long rows, a boy with one horse will plant an acre an hour.

Be governed by weather and soil as to depth, but do not plant over an inch deep as a rule; often less depth will do. On some soils it will do to pack the ground over the seed, but often this is a harmful practice. I am strongly in favour of machine planting, but no matter what system is used, be sure to have the ground fresh and mellow, and plant plenty of seed. To this end, do not

be limited to exactly two pounds per acre. Properly planted, the cane is half tanded. Before the young cane plants appear, run a light harrow over the field, regardless of the rows. A smoothing harrow is excellent. So is one made of brush, or a flexible drag. Don't fail to harrow every three or four days, for several weeks after planting. When the cane is up, follow the harrow with the hoe, and uncover the plants that may have earth on them. Many will shake their heads at the suggestion of the harrow in the cane-field, but years ago, when its use in the corn-field was recommended, unbelievers were just as numerous. I claim that, beyond all cavil, the expense of raising a cane crop can be reduced one-half by the use of a light harrow in cultivation, but the ground must be in as fine tilth as for onions at planting time. Of course, the harrow will tear out some cane plants, but this loss should be anticipated by extra seed at planting time. The harrow can be run both with and across the rows of cane, and can be used until the cane is six inches high, then use the two-horse cultivator, as for corn, the rest of the season. The old practice of hoeing cane must be given up, just as the hoeing of corn has been. By using the harrow, as directed, the weeds that spring up are killed when just starting. When the last harrowing is being given, let the men follow with hoes and dress out the cane, thinning it where necessary. The equivalent of one stalk for every six inches, in drills that are three and-a-half feet apart, is sufficient for a large yield of syrup.

As a summary of the above:

1. Test the seed before planting, and do so early enough to secure more if that should fail.
2. Have the ground in good heart, but not made rich from rank manures.
3. Prepare the ground as you would an onion-bed, and have the soil freshly stirred on the day of planting.
4. Plant plenty of seed.
5. Use a light harrow frequently, beginning its use before the cane is up.
6. Try to use the hoe only for uncovering and thinning the plants.—*Farmers' Review.*

THE CULTIVATION OF THE POTATO.

IT is commonly thought that any person can grow potatoes, and while it is true that any person that can fit the soil and cover the seed, and cultivate the ground so as to keep down weed and grass, can grow the tuber, yet it is equally true that few farmers in our country grow the potato plant successfully. Perhaps the most obvious reason for the uncertain character of the potato crop is due to the fact that the potato plant is an exotic, that is, not originally native to our climate. Where the potato plant, named by botanists *Solanum tuberosum*, grew wild in its native soil, in South America, it was found high up from the sea level in the ravines of the mountain sides and upon the table lands, where, according to Humboldt, the temperature only varies from 55 to 80 degrees by our common thermometer. This gives only a change of 25 degrees in a whole year, and as the plant makes its entire growth in less than half a year, it has been stated that during that time the range of the thermometer does not probably exceed 15 degrees. It will be seen that this condition of the temperature we cannot have; for after the tuber is planted in early spring the temperature is liable to vary 70 degrees, from 30 to 100. The only wonder is that the potato plant stands the strain of its changed conditions as well as it does. One lesson that may be learned from this is, a naturally cool soil, other things being equal, should be selected for the potato. Hence a north inclination is better than one to the south. Plant corn on the south side of the hill, and the potato on the north side. But if there are no hill sides, but must grow the crop on the almost level prairie, select a spot that does not hold water, a few inches down, as is the case with a thin soil in a sub-soil of clay.

Another cause of failure in the cultivation of the potato arises from the fact that while the plant is a rank feeder, its roots cannot run far for food. Hence it needs a naturally rich soil, or one made so by proper manure. But is a proper manure for this crop? And when should it be applied? The plant is not as particular as to kind of manure, as it is to its condition. Fresh manure from the barn-yard, whether made by horses or cattle, is not well adapted to the healthful growth of this plant; while old, well seasoned, of almost any kind, may be used to advantage at time of planting. A long experience at the East taught the writer that the best way to manure the soil for the potato is, to apply a heavy dressing broadcast the year before, and use none at the time of planting. Our choice would be to apply from 10 to 20 or 30 cords of good barn-yard manure to land having a good stand of red clover. Haul it on during the winter or before the frost is out in early spring. As soon as frost is gone spread evenly. Two heavy crops of hay taken off the following summer, or one for hay and one for seed. Then plough deep during the following fall, and turn well under all the after math, not pasturing it at all. The next spring, as soon as the ground is sufficiently dry, run a cultivator as deeply as it can be done without disturbing the soil. When the soil is well pulverized, open furrows five to six inches in depth if it is practicable, and three feet apart for erect growing early sorts, and three feet six for peasehallow, or other tall viney kinds. If the object is to grow the largest possible crop from the ground without regard to economy in labour, plant in the open furrows, dropping the seed about 18 inches apart. But if square feet of ground are more abundant than strong hands, then plant the tubers crosswise of the rows, and the same distance apart that the furrows were opened. In either case the seed may be readily covered with an adjustable cultivator with two covering teeth in the outer end of the frame, running crosswise of the furrows. Or a light harrow with short teeth will answer every purpose.

AMOUNT OF SEED.

If planted in drills, use only a two-eyed piece at each 18 inches; if in hills, use two such pieces for each hill. Some prefer whole tubers at each place. But it has always seemed to the writer to be a waste to do so; for if the tuber is cut to single eyes every one will germinate, and if two-eyed pieces both will usually start well. But if whole tubers are planted before sprouting much, then but a few of the most forward buds will grow, while the others will remain dormant and soon die, acting as though conscious they would not be needed.

It will be seen that one piece in drills, or two in hills, at the distance mentioned will take the same amount per acre, which will require, if large tubers, from six to eight bushels, and if smaller ones, correspondingly less.

The most suitable soil for the healthy growth of the potato plant is a sandy loam, and if mixed with the fine gravel or slate it is no objection; but the soil should contain but a small per cent of clay, unless it is thoroughly mixed and well drained. If the soil contains considerable lime it is no particular damage, and if it contains potash or phosphorus all the better. A small handful of wood ashes thrown around the young plants just as they break ground will greatly increase the soundness and table quality of the crop, and will well repay where they can be procured for the price of half a bushel of the crop for each bushel of ashes.

PREVIOUS CROPS.

It is mentioned above that a clover sod is to be preferred. But as that is not always to be had then plant in a timothy, or June grass—i.e. Kentucky blue grass, or white clover sod, in all cases treated as mentioned for clover for a large crop. In case no preparation has been made the previous year, then plant on stubble ground after wheat, oats or rye. A very good preparation is to turn under a field of rye, the last week in April or first of May, and after carefully harrowing with a short, fine-toothed harrow, plant at once. A good crop may be looked for.

There is great objection to high hills in a hot climate. On a dry or well drained soil plant deep, then never use the plough among the growing plants, but run a narrow harrow or cultivator frequently, but make no hills. The level surface, well stirred, will not dry out and cause the plants to suffer like the hilling process.

If the ground planted is so level as to make it desirable to give it surface drainage, then run a small double-mould broad plough at the middle between the rows, one way only; having arranged the rows so that a descent from it may be secured. Tile draining is, of course, better, but is often lacking.—*Farmers' Review*.

FIBROUS PLANTS IN MEXICO.

ANYTHING and everything connected with the supply of fibre, whether for textile purposes, cordage, or for paper, is becoming of more interest almost daily. A recently issued report on some fibrous plants of Mexico, with notes on their habits, will therefore be read with interest. The country under review, where the plants referred to are found, is discussed in the following paragraph:—"The river of Monterey, a tributary of the San Juan, rises in the Sierra Madre, and has for its cabeceiras numerous small springs at a point known as the Potrero de Santa Catarina, say twelve miles west of Monterey, and very near the railway. A potrero or pasture here means a plain encircled by high mountain walls, to which there is but one entrance. The aperture to this is difficult, and the means of conveyance pack mules. This potrero is very extensive from north to south, entering the heart of the mountains. It has many sinuosities. On the right and left from this central desfiladero or defile there are others running east and west, called canones or canyons. Each has its special name, and there are a dozen or more. The surrounding scenery is majestic. High peaks, cliffs, gorges, chasms, great scars, and impending boulders on the river fronts of the encircling mountains. Huge pine trees adorn the mountain side and crown the top. From here there is a short foot-route vi' the Escaleras Canyon to Saltillo. There are, say, thirty small farms in this potrero, and they are irrigated by the numerous springs. The products are sugarcane, corn, wheat, barley, sweet potatoes, squash, chile, water and musk melons. Here the 'lechugilla' grows abundantly, and much of the fibre called *ixtle* is made."

This plant, the lechugilla, seems to be that known to botanists as *Bromelia pita*, and, together with the maguey or *Agave americana*, and the *Palma criolla*, have attracted much attention both in Mexico and abroad, in the United States, and Europe. All the plants grow along the line of the Mexican National Railway, above an altitude of 1,000 feet, and throughout the districts contiguous. They are very prolific, growing wild upon the plains and mountain side, between Lampagos and Saltillo, and especially so at Bustamante and the Plaxcala Pass near by, where there is excellent water power from a stream flowing from a mountain spring, which has a volume of two square yards, with a fall of 200 feet in five miles. They can be gathered at all points along the line, and conveniently transported in vast quantities to an eligible locality for disintegration and shipment. The salubrity of any point on the line of this railway is said to be equal to that of the great health resorts of the world, and all, owing to temperature, altitude, and high condition, are far remote from yellow fever and other infected districts, and well suited for mining operations, manufacturing centres, and populous districts.

The lechugilla—the literal translation of which is said to be small lettuce—is described as furnishing a coarse and strong fibre from 18 to 24 inches in length, and is used for making sacks, mats, ropes, brushes, &c. It is the *ixtle* fibre of commerce, and is exported in increasing quantities from Mexico to the United States and other countries. An infusion of the root has strong

detergent properties, and is extremely valuable for woollen clothing. It is said not to have the effect of discoloring, but, on the contrary, "articles likely to fade may be washed with an infusion of the root in safety." Though it seems that the principal use of this fibre in its native country is for rather coarse purposes, it has been described as of extreme fineness, equal to the best China grass, and capable of being manipulated into the finest fabrics.

The maguey, century plant, or agave as it is variously called, is described in the report we are considering as being quite as abundant as the lechugilla. The maguey, as is well known, is the (*Agave Americana* L.) The heart of the plant yields "agua miel" or "wort," and this, when fermented, becomes pulque, an intoxicating liquor in great request by the people. The roasted heart is mescal, and this, when pressed in a mill, yields a liquid by distillation, called 'vino de mescal.' It is a strong spirituous liquid, as clear and colourless as spring water. A fibre is extracted from the leaves of the plant by simply wringing them, which is said to be an excellent antiscorbutic, and has been used with most satisfactory results in cases of scrofula. The fibre can be obtained from five to even six feet in length. It is very fine, and the Mexicans weave it into fine textures. It is said that shoemakers use it to make their best thread, and the writer of the report says he has seen it "wrought into handsome money bags, ornamental baskets, &c., and then tinted with various colours. So far no machinery has been invented, or at least the Mexican people know of none, suited to break, hackle, and prepare this product. They do it in a cumbrous way by hand."

The following is given as an illustration of the extent of agave plants to be found in a given area. At Santo Ysabel, a station between Lampagos and Bustamante, the railway runs for a distance of about six miles over the land of a certain Don Solome Botello, who distils a great quantity of vino mescal. "To give an idea of the great abundance of maguey growing spontaneously on his land—all without cultivation—it is but necessary to say that 20,000 plants were destroyed in clearing the ground for the right of way. Lately, while making a short excursion across his lands, in company with the general manager and general superintendent of the road, he called our attention to the great loss of maguey leaves in taking the heart of the plants for distillation. For every plant cut 25 great leaves were left strewn to rot upon the ground, or 5,000 leaves to each 200 plants."

The "palma criolla" (*Oreodoxa regia*) is a tall-growing palm, often planted in avenues. It is described as being very plentiful. The fibrous leaves are used to thatch the ordinary Mexican hut, or if straw or other material is used for the thatch, it is nearly always clad on by strings formed from the torn leaves after being heated; this string, indeed, constitutes the common twine of the country. The fruit is somewhat similar in appearance to the date, and is some times eaten. It is also distilled, and from it a quantity of *aguardiente* or rum is made. "There was quite a large distillery of this kind near and northward from Salinas on the railway. This plant or tree has lately excited much attention, as throughout it is of a fibrous growth, trunk, leaves, and all, and some are experimenting with it with a view to the manufacture of paper."—*Planters' Gazette*.

LIME.

BY SIR J. B. LAWES, BART. LL.D., F.R.S.

THE report of the Directors of the Scottish Chamber of Agriculture contains some very interesting tables respecting the exhaustion of lime.

The directors have brought together in one page the opinions and experience of the great body of the farmers of Scotland; and according to the evidence thus supplied, the shortest period of time during which a full application of lime is said to last, is seven years; while thirty years and over is stated to be the longest period.

When we consider that the influence of lime upon a soil which is naturally deficient in this substance, is due to several distinct causes; and further that the after-treatment of the land which has received the lime differs much in different cases, we have no difficulty in understanding that there must be considerable variations in the periods of time during which the beneficial effects of lime will be apparent.

Two of the crops which are grown at Rothamsted in our ordinary rotation—roots and clover—contain large quantities of lime in their ash, and when potash is not abundant in the soil, they possess the property of utilizing this lime in its place.

The ash of leguminous plants growing in an ordinary pasture which had been well supplied with potash, contained 32 per cent of potash and 22 per cent of lime, but no pasture where potash was not supplied, the ash contained 32 per cent of lime and 14 per cent of potash. Lime therefore economises the use of potash.

The first application of lime to moor land, or to pastures which are deficient in lime, is often followed by a growth of white clover so abundant as to have led some to the conclusion that the plant was spontaneously generated in the soil! It may be observed, however, that it is only plants with creeping roots which can so rapidly cover the ground; a similar instance in the case of arable land may frequently be observed in the equally rapid covering of the soil by couch grass; this being a graminaceous plant can find in all soils an abundant supply of its own proper food—silica; but lime in many soils is by no means abundant, and if the supply is insufficient, a liberal dressing is essential, not merely for the purpose of furnishing the lime which the plant takes up, but also to enable the roots to be in constant contact with that substance.

I may say that, although the amount of lime dissolved, and the water is considerable, still the necessity of the application after a few years appears to be rather due to a descent of the lime to a lower level in the soil, where it is less accessible to the roots of the plants.

Lime also acts as the medium by which nitrification takes place; and the almost entire absence of nitrates in the water passing through the peat soils in Scotland—which abound in nitrogen—must be mainly due to the absence of lime.

A reference to the returns in the table shows that the effect of lime is most durable upon pastures that are grazed; that its effects are very good upon virgin soil; that it lasts longer upon good, than upon bad, land, and upon clays and heavy loams, than upon light land.

The amount of soil nitrogen which is nitrified each year must depend somewhat upon the amount that the soil contains; but where each application of lime is attended with less benefit than the preceding one, we may feel tolerably sure that the resources of the soil have been too largely drawn upon, and that the export of fertility has been too great.

Lime therefore acts in a double capacity—it furnishes an important ingredient in the food of roots and leguminous plants; and in addition, it furnishes the key by which the stores of organic nitrogen in the soil are unlocked, and rendered available as the food of plants. It is in this latter capacity that its functions are more liable to be abused.

As lime does not furnish any of the more important, or of the more costly ingredients which plants require to form their structure and seed, it is quite evident that these must be derived from the soil: this being the case, if the views of those who hold that agriculture should be carried on without any reduction of the fertility of the soil are correct, it is evident that an application of lime should be accompanied by an application of all those ingredients which are carried away in the crops, or by feeding with stock.

My own opinion is that soils are generally competent to yield a certain portion of their fertility without injury, and that practical experience of the particular district will be the best guide for deciding the amount of fertility that may be thus removed.—*N. B. Agriculturist.*

ROTATION OF CROPS.

WHAT is the true theory of a rotation of crops? Doctors differ on the point. There is a school in this country that reduces the question of the fertility of the soil to a matter of give and take. Here, they say, is a general table of analyses of soils, and also of cultivated crops; of certain manures, &c. Nothing easier than to calculate the total yield of a crop, to know the quantity of phosphates and of potash, &c., carried off. The analysis of the manure will enable the quantity of those salts to be estimated and requisite to be returned to the soil; if in excess, the richness of the land will be augmented. It is further laid down that cereals and industrial plants draw largely on the soil for nitrogenous principles, but as these crops are succeeded by forage plants the deficit is made up by the intervention (hypothetical) of atmospheric nitrogen. Further, the necessity to practice a rotation of cropping is explained by plants not requiring the same mineral substances, so that what one leaves the other will appropriate, and that, after a lapse, say of five years—thanks to periodical manurings and dissimilarity of tillages—the alternate exhaustion and the renovation of the soil will be found equalized.

Now, what is our stock of precise, demonstrated knowledge on this subject of rotation? It is exact, that the mineral food removed must be restored. By the successive cropping of lands in Slilly with wheat, the phosphates had been exhausted, and the soil has become impoverished. The same fact was in process of realization in the north of France, till M. Coenunidor called attention to the necessity of employing phosphates, and since fertility has returned. Now for plants, as for manures, there is no constancy either in mineral or nitrogenous, or even in any other elements. Analysis shows that a large number of different manures vary in composition, from one to four times in the case of the same element. Similarly for plants; wheat, for example, where the percentage of nitrogen, as in gluten, varies from one to three. There are analogous differences for the potash and phosphoric acid carried off. Hence there is no mean, no Procrustean standard, that can be declared off-hand applicable to a special soil. Strictly speaking, each particular case demands a new analysis. One field may produce a forage five times more nutritive than another.

A popular error exists, that Boussingault asserted forage plants take nitrogen directly from the air; even his latest experiments demonstrate the exact contrary. Then the attempt has been made to explain the restitution of nitrogen to the soil by the agency of meteors and rain. It is a fact that ammoniacal salts and nitrates are constantly present in the air, and conveyed, along with other saline and dust matters, to the soil by the rain. But the latter falls on the just and unjust alike; upon all cultures indiscriminately, not upon any particular rotation, and not specially on forage plants. It is assumed, but not proven, that electricity nitrifies the osote of the air in the interior of the soil, by a union with hydro-carbonaceous matters; or effects a similar end in the interior of plants, by their starch, sugar, &c. We know, however, that the osoteous matters in the soil can be nitrified, but that is not an augmentation of richness; also, Cavendish has shown, in 1784, that an electric spark traversing an atmosphere enriched with oxygen, can produce nitric acid. Now, if electricity makes

ammoniacal salts and nitrates in the atmosphere, that intervention is for all rotations and crops alike.

It may be laid down as an axiom, that every system of culture which does not bring, from an outside source, the materials, whether nitrates, phosphates, or potash, &c., rare in a soil and carried off by the produce, must ultimately suffer in fecundity. There is a necessity, apart from these food considerations, to rotate crops; the plan affords the means for extirpating weeds, for cleaning the ground, and of destroying insects, since if the latter, peculiar to a distinct crop, be deprived of its special food for one or two years, it must die of starvation. To keep a soil rich, depend upon manures, rather than on the air.—*Farmers' Review.*

THE WHEAT TRADE.

THE East Indian Railway Company have given the B. B. and C. I. Railway Company notice that from the 1st May, when the reduced rates under the recent arrangement for grain and seeds sent from Delhi to Bombay via Sabarmati, come into operation, their own rate for grain and seeds from Delhi to Howrah will be reduced also from Rs. 70 to 65 per 100 maunds. The comparative charges will then be from Delhi—

FOR WHEAT.

| | |
|-----------|-------------------------|
| To Bombay | 11 annas per maund. |
| To Howrah | 10 2-5 annas per maund. |

FOR OTHER GRAIN AND SEEDS OF SAME CLASS.

| | |
|-----------|-----------------------------|
| To Bombay | ... 11½ annas per maund. |
| To Howrah | ... 10 2-5 annas per maund. |

The East Indian Railway propose making a further reduction, on and from 1st June, on this description of traffic from both Delhi and Agra to Howrah, to Rs. 60 per 100 maunds, or to, say, 9 3-5 annas per maund. The present rates for wheat from Delhi are—

| | |
|-----------|-----------------------------|
| To Bombay | ... 13½ annas per maund. |
| To Howrah | ... 11 1-5 annas per maund. |

the difference being 2 3-10 annas. Mr. Wood, the agent of the B. B. and C. I. Company, has urged, and the Bombay Government and the Chamber of Commerce here have deemed it reasonable, that the difference in rate by the two routes might be limited to one anna per maund. The ultimate difference now adopted by the East Indian Railway is equal for wheat to 1 2-5 annas per maund, or nearly one anna (9-10) less than the present difference, which should be greatly in favour of Bombay, the route being so much shorter. The actual reductions made on both routes are, however, greatly to the advantage of the country and its trade. The reduction in the rates of the East Indian line was anticipated by Major Baring in his Budget Statement as a probable result of the reduction of the through rates from Delhi to Bombay. The Finance Minister estimated the practical result of the lowering of the rates to be, that Indian wheat would be laid down in London at a reduction of rather more than 1s. 6d. per quarter. This will, it may be hoped, encourage shippers of Indian wheat to see what further reduction of expense may be achieved, so as to enable the competition with American wheat to be carried on under more equal conditions.

As we have already mentioned, a conspicuous place was accorded in the recently issued Financial Statement to the conditions under which the export trade in Indian wheat may be maintained and developed. The English market, which takes about half the total amount—20,000 000 quarters, or nearly a million tons—from this country, is ruled not by the outturn of English soil, but by the supply from America. Major Baring gave some interesting information bearing on this question in a section of the Statement which may be turned to with advantage. We can supplement that information with facts and figures of no less interest which will be full of suggestion to all who wish to forecast the future of the Indian wheat trade. To-day we shall confine ourselves to the conditions obtaining in England, and to the enormous advantages possessed by the American supplier. We shall on another occasion glance at the elements in favour of the Indian producer and exporter; just now it is sufficient to bear in mind that Major Baring is inclined to attach considerable importance to the fact that while protection saddles the American farmer with a tax of upwards of 40 per cent on his implements and on most articles not indigenous to the country, the Indian producer and exporter are in the full possession of all the economic advantages of free trade. Bearing that fact in mind, the circumstances, which are to all appearance so overwhelmingly against our wheat export trade, need not alarm us quite so much as at first sight they might be calculated to do.

The average yield of a wheat-field in England is generally supposed to be about four quarters an acre, and the rent of such land may be put down as 35 shillings an acre. But wheat cannot be grown for a series of years in succession: it is an exhaustive crop, and requires careful treatment of the land to maintain a good average yield. The crops which are grown in rotation with it are of inferior value, and help to bring down the profit which

is derived from the farm; and taking the effect of bad and wet seasons into consideration, the gross produce may be taken as three quarters of wheat all round, which at 60 shillings is a gross return of 180 shillings an acre, and as the rent is 35 shillings, which is one-fifth of the gross produce, the remaining four-fifths are left to pay the expenses of farming, and the ordinary profit of the farmer, which is considered to be 9 or 10 per cent. The capital employed is nominally £10 an acre, and the profit expected may therefore be taken as £1. For the purposes of the income-tax the farmer's profits are assessed at half the rent, and as 20 shillings an acre is a little more than half the rent, it may be assumed that the profit is not under-estimated. Therefore, if 35 shillings be deducted for rent and 20 shillings for the farmer's profit, the remainder of 125 shillings an acre may be taken as the expenses of English farming under present conditions. These expenses are not liable to much decrease; they consist chiefly of labour and manure, and the cost of both these items is liable to increase; and if by any chance the gross money return of 180 shillings an acre is permanently lowered, then the obvious effect will be that economy must be practised in rent, or the ordinary profits of the farmer must be decreased, or both. The farmer is not likely to allow his profits to be reduced, and the necessary consequence will be a decrease in rent. The struggle which is now going on in Ireland is for the reduction of rent, because it interferes with the profit which the farmer expects to enable him to live and to thrive, as it has been judiciously expressed. The same struggle is silently occurring in England, but the remissions which landlords have voluntarily granted are likely to become permanent, and where new leases are entered into the rate of rent has been decidedly lowered. It is plain that the general feeling is that the money return for produce will not be as high during the next series of years as it has been in the past, or in other words, that 60 shillings a quarter of wheat is not likely to be secured. The cause of this is not the temporary effect of two or three wet seasons in succession which has destroyed or reduced the produce of the land, but the fear of American competition. American wheat has been sold at 44 shillings a quarter in Liverpool, with profit to the importer, and what has occurred is likely to occur again. This fact has demonstrated that English farming is in danger. If English wheat can only be grown at a dead cost minus rent of 120 shillings for three quarters, and that quantity of American wheat can be sold in England at 132 shillings, there is only 7 shillings an acre left for rent and for farmer's profits. It is quite obvious that under such circumstances he cannot afford to pay a penny of rent, and that his own profit must be reduced from 20 shillings to 7 shillings an acre—that is, 3 per cent on his capital. And if this is to be the result of growing wheat, the farmer would do better, if he cannot grow something else, to retire from farming altogether, and invest his money in consols or Indian 4 per cents. The question of rent resolves itself into the question—at what cost can American wheat be grown and laid down in Liverpool? It has been done at 44 shillings a quarter, and it is to be considered whether this price can be maintained as a rule, or whether it is liable to be increased or decreased. Now let us turn to the American wheat lands and their probable future.

Mr. Williamson, M.P., a large grain merchant of Liverpool, considered it necessary in connection with his business to visit the American wheat-lands, and discover the cost of production, and what was to be expected from the competition of this wheat. He went from San Francisco to Wala-Wala near the Sierra Nevada, and found the most astonishingly fertile region that any one could imagine. There was a stretch of wheat-fields running eastwards to the Blue Mountains as far as the eye could reach on all sides. The whole expanse was covered with wheat, and he found that the average produce was 32 bushels to the acre. The country is almost unknown and untrudged, and will produce wheat in illimitable quantities. It is sold on the spot for less than 2 shillings a bushel, but the cost of carriage to the coast is so high that until greater railway facilities are given we have not too much to fear from this region. But even at present the farmers make a living without getting rich, and doubtless the country will be opened out in time, when its wheat could be sold in Liverpool for 35 shillings a quarter. It is capable of growing 100 millions of bushels of wheat per annum if there were facilities of transit, and the soil is such that wheat has been grown for 22 consecutive years with a steady yield of 30 to 35 bushels an acre on 10 to 12 feet of alluvial black soil which is inexhaustible. Add to this, the attractions of a climate where peaches and grapes ripen in the open air, and we may easily infer the future of this happy valley. In the Sacramento Valley, 200 miles by 40 miles, the soil is extremely rich, the climate delicious, and the cost of cultivation a bagatelle. They don't require to put up the wheat into sheaves; they take the ears of corn and put them into a pile in the middle of the field, where they are threshed; and the wheat is put into sacks for shipment. The straw is burnt or trodden down by hogs or cattle. The corn may remain ripe in the field six weeks or two months until the farmer can undertake it, and he does not incur a great deal of expense through changeable weather. The consequence is, that the cost of production in California is extremely cheap; almost cheaper than in any other part of the United States. The wheat is shipped to England, and would cost 40 shillings a quarter. The Red River Valley is as flat as a table, no trees except on the banks of streams; the land is easily cultivated; the soil is good, not very deep, and nothing to compare with California, but excellent soil two feet deep and possessing great capabilities. The part of the valley in Minnesota is the best, and has the advantages of two markets, one at Chicago and the other at Minneapolis, where the great flour mills are built. Mr. Dalrymple's farm is in this valley, and his operations are gigantic. He commenced with 5,000, and now farms 30,000 acres, and on an average he has 22 bushels to the acre, which costs only 12 shillings a quarter to grow, although the small farmers cannot grow wheat at less than 16 to 20 shillings a

quarter. The carriage to New York and thence to Liverpool costs about 13s. 6d. a quarter, and the commission charges and handling may be put down as 3 to 4 shillings a quarter. Red River wheat can thus be put down at Liverpool for 50 to 55 shillings a quarter. Mr. Williamson had a preconceived notion that American wheat could not be grown for less than 44 shillings a quarter. But he frankly admits that after he had been in those fertile valleys and had travelled over California, Oregon, Wala-Wala, and the Red River, he was convinced that they could produce enormous quantities, and that the English farmer has no chance with regard to wheat, although there was a great field before him in dairy produce.

The wheat in America is of two kinds—the spring wheat is supposed to be inferior to the English grain; the fall or winter wheat is undoubtedly better than the spring wheat, and would equal or surpass home-grown wheat. Mr. Pell, M.P., and Mr. Hedd, who were sent to America to examine and report upon the farming competition of America for the Agricultural Commission, travelled over a great part of the States, and gave their opinion that wheat is giving place to maize in the older States, but that it is extending rapidly in the vast prairie lands of the north and west, where the average return of late years has been 20 to 30 bushels. There is an enormous tract of prairie yet unbroken, which will be devoted almost exclusively to wheat, which is the first crop they grow. Wheat is more or less being abandoned in the older States, because they cannot stand the competition with the prairie lands, and its successful cultivation depends more upon the season than on tillage. Besides, as population increases in these parts, there is a greater demand for dairy and vegetable produce, which is more profitable; and as the soil is getting exhausted, wheat cannot be grown except in rotation and with the help of manure, which increases the cost of cultivation and makes it impossible to compete with the prairie wheat, which can be grown for many consecutive years without manure or any sensible decrease in the yield. Maize is preferred in the old States, because the return depends upon tillage, and is therefore more certain, and it serves to fatten pigs. In the prairies they cultivate, on strictly economic principles, the greatest area which can be cultivated under proper supervision, and employ machinery admirably suited to their purpose. The ploughs are perfectly adapted to the land, and their reaping machines are remarkable. They have machines for gathering the wheat and self-binding with wire, but they can now do it cheaper with string; it is a perfect machine, and makes a difference of two or three bushels saved in waste where men are employed. Mr. Dalrymple, who owns the 30,000-acre farm, takes advantage of the splendid climate, and does not make his corn into sheaves, and saves the expense of building them into stacks. He uses an automatic reaper, and lets the wheat lie until it is carried to the threshing machine, and thence to the granary or elevator, as it is called, at the railway station, where it is sold, and sent off at the rate of 1,000 bushels a day, which is something extraordinary. The climate is almost always to be depended upon, and the cultivation is exactly suited to the land. Light ploughs and double ploughs on wheels are used, which get over something like 3½ acres a day. One man may look after two ploughs with three horses each. Mr. Pell says: "I saw him start; he left his own team and jumped on to the seat of the first plough, got it into the furrow and started, and then turned back and got to his own team, and followed as quick as he could. The shot of that man's work was a mile long, and I waited until he got to the end, and saw him jump off within 40 or 50 yards of the end of the shot, and get upon the leading plough, which he turned at the end, and then he ran across to his own plough, and so got back again." Then besides the advantages of climate and the ease with which immense areas of stoneless plains can be cultivated and harvested with the best possible machines and at the lowest cost, the whole object of the railway companies in the Western States is to accommodate the farmers. In England the object is to accommodate the traffic between large towns, but in America the first object is to develop the land, and directly the line is built an elevator will be put up, and a water tank, and very likely a saloon, and at that elevator will be some representative of the great merchants who announce "Cash for wheat." With all these advantages on boundless farms the statement of the Americans themselves that they can grow wheat at 12 shillings a quarter, is not improbable, but allowing for exaggerations, it may be accepted as certain that they can grow it and deliver it at the nearest railway station for 18 or 20 shillings a quarter. The wheat trade centres at Chicago, and the carriage from the farms to Chicago, which may be a distance of 400 or 500 miles, is put down at 6s. 8d. a quarter, while the carriage from Chicago to New York, which is 1,000 miles, is only 5s. 2d. a quarter. At present there is no railway competition west of Chicago, but in a short time, considering the rapid rate at which the country is being settled, this high charge for carriage to Chicago will decrease. Add the freight to Liverpool, 5 shillings a quarter, and commission charges, and wheat may be put down in England at 40 shillings a quarter; and as it has been sold for some time at 44 shillings, it will be seen that this price gives a substantial profit to the trade; and by cheapening the carriage, for which there is room, wheat can be put down at 35 shillings, or even at 32 shillings, which is the lowest estimate made. Mr. Pell does not believe these low figures will be reached, but he frankly admits that if he were going to farm land in England, he would calculate upon wheat being 42 shillings to 44 shillings a quarter. Obviously the English farmer has no chance with wheat, and farming must be entirely revolutionised to meet the competition of America. And India, if she is to retain her present position in the English market, and still more, if she is to improve it, must be prepared to encounter American enterprise with similar methods—railway development, reduction of rates, and greater economy in the handling of the grain between field and port.—*Bombay Gazette.*

THE ANTISEPTIC ACTION OF SPONGY IRON.

CACAO.

In a letter to the *Journal of the Society of Arts*, Mr. James Hogg says:—

Dr. Bischof, in his communication of last week, says, with reference to my letter on "The Chemical Analysis of Water" of the 9th instant:—"Mr. James Hogg renews a discussion which it might have been expected was carried far enough at the Institution of Civil Engineers to prove that he made a mistake." I am quite unable to discover the "mistake" he alludes to; and there certainly was no mistake on my part of the utter failure of the spongy iron filter to kill, or, as Dr. Bischof puts it, "destroy the germs of putrefactive bacteria; and possibly those of epidemic disease." My experiments, performed with due care in every way, show that the spongy iron filter will not destroy infective germs, and I must confess that I entirely fail to see the relevancy of the preservation of butter, which he imports into the question, with this of "the chemical analysis of drinking water." It is a well-known fact that butter and animal substances, if preserved from atmospheric contact, can be kept sweet for a lengthened period. I repeat what I said at the meeting of the Institution of Civil Engineers, that my experiments were conducted with great care and with a desire to form a perfectly honest opinion as to my results and no more. I have since repeated my experiments with every precaution, and upon a specimen of water sent to me from Antwerp, collected under chemical supervision, and at this cold period of the year, the temperature of the water being only 38° Fahr., and these have also broken down under the gelatine and microscope tests. I am perfectly justified, then, in concluding, it is not because Dr. Bischof tells us that it is the object of the spongy iron filter "to destroy certain specific poisons," that the spongy iron filter will actually accomplish this, and secure a constant supply of drinking water.

The spongy iron filter does exert some chemical or mechanical action in water; nevertheless, like other filters, it is only to be actually depended upon for separating the coarser matters suspended in water—and which are, for the most part, harmful—from those that are finer and, probably, more dangerous. This will naturally impart a bright and brilliant look to almost any water; but water so treated may yet contain the germs of death, and arrangements, devised with the best intentions, for their complete exclusion will not avail much, as the seeds or germs of bacteria are so minute and impalpable that they are carried about by every breath of air, and a single drop of water is sufficient to start them into life. Water is their natural habitat; in it they live and multiply to an almost incredible extent. What then can we expect "common sense" to do for us in guarding filters in daily use against re-infection? These specific poison germs exist in the extremes of cold and heat of strong anti-corrosive fluids; why then does Dr. Bischof expect spongy iron shall kill them? A saturated solution of carbolic acid, although apparently effective for the destruction of some forms of micro-organisms, will not destroy the germs of a specific bacilli. Indeed, some of the latter, after immersion for a month in fuming nitric acid, I have discovered very little the worse for confinement in their new and extraordinary conditions of life.

Dr. Bischof employs, he tells us, "covered reservoirs," both in Antwerp and London, for the purpose of preventing re-infection by suction, during filtration of the water. Does he seriously believe that covered reservoirs will remove all chance of infection by atmospheric contact, for all time, and during each stage of his water filtration? I fear he will not gain much by his covered reservoirs.

What, then, is the proper course to pursue? That which I have so often recommended. We must draw our water from natural sources, which are neither contaminated nor contaminable. Our only security is resort to deep wells; and the drinking water of communities and individuals should only be taken from such sources. In London this could very easily be accomplished, as within a circuit of thirty miles there are 100,000,000 gallons of pure spring water running to waste. Here, then, is the remedy against pollution; and a bountiful supply, supplied by nature, for all culinary and drinking purposes. Why should London be debarred from tapping this source of pure and wholesome water?

One last word with respect to spongy iron filters. I notice that spongy iron exerts a detoxicating effect upon water; and, also, on standing a glass bottle of filtered water by for a few days, a considerable deposit of red oxide takes place. There is, probably, no great harm to be apprehended from the latter; but water bereft of its oxygen, is neither very palatable nor perfectly wholesome. For this reason it becomes absolutely necessary once more to restore this important element—oxygen—to spongy iron filtered water, and this is done at the Antwerp water-works.

It is now placed beyond a doubt that all the various processes adopted by chemists, more or less, miss their mark. They all, indeed, destroy without discovering the more pernicious micro-organisms contained in their specimens. This I have insisted upon and pointed out, and it has been once unmistakably demonstrated by the Medical Department of the Local Government Board. Dr. Cory has directed a series of experiments which clearly prove that a chemical examination will not distinguish between an excremental pollution of water and that taken from a pure source; so "the lesson is taught us afresh and significantly, that while we must ever be on the watch for the indications that chemistry affords of contaminating matters gaining access to our waters, we must go beyond the laboratory for evidence of any drinking waters being free from dangerous organic pollution. The chemist can tell us of impurity and hazard, but not of purity and safety. For information about these we must go, with the aid of what the chemist has been able to teach us, in search of the conditions surrounding water sources and affecting water services."

CACAO CULTIVATION IN TRINIDAD.—In the first half of 1882, the exports of cacao had risen to over ten millions of pounds against an average of eight millions, and the *Trinidad Chronicle* states:—"The laying out of new land in cacao goes on unceasingly, as it has been doing over the last 13 or 14 years, the great majority of the plots, small at first, owned by small people *ci-devant* labourers and contractors, and cultivated by themselves, but by degrees forfeited to the merchants to whom they are indebted for advances, and by amalgamation converted into good-sized properties counting acres by the hundred and (the cacao) trees by the tens of thousands. There is no movement corresponding to this in cane; and the opening of cane estates on any scale—and a large one, *ab ovo*, is the rarest of *rara avis*—goes on slowly indeed. It cannot be done without capital, a capital of thousands sterling, while a very small purse of savings will give a man courage to buy and lay down, in cacao and provisions, a little plot of ten or twenty acres. Yet it is pleasing to note that where a new line of road cuts through virgin land, as at Couupia, by the railway, buyers start up from the ground as it were that no one dreamt of, men in the town successful in business or trade whom no one had previously credited with a taste for cultivation, yet who, on being tested, have been found to be gifted with a somewhat Mechian capacity for the pursuit quite equal to, and in some respects possibly better, than old clod-plodders to the manner born, carrying into the new practice the habits of foresight and perseverance that had gained them their first successes, and yielded them the means to enter on an untried venture."

EXPERIMENTS IN COCOA CURING.

[THE following letter, addressed to a cocoa planter, has been placed at our service for publication.—Ed, *Times of Ceylon*.]

Colombo, April 2, 1883.

DEAR SIR,—I have to apologise for having delayed so long my promised report on the experiments I made with cocoa pods you were so kind as to place at my disposal; one thing or another came in the way of my putting the results on paper. Your letter of the 31st ultimo hastens, by a few days, the letter I intended to write to you. One of the chief objects I had in view in asking you to lend me some cocoa pods was to ascertain whether I could hasten the process of fermentation, by the application of a regular and constant higher warmth, than that of the atmosphere. I am sorry to say that all my experiments in this direction were complete failures; the result, therefore, is, that instead of preserving the pink colour of properly fermented beans, all I experimented with are very dark and coated, so far as the outward appearance is concerned. I attribute this complete failure in a great measure to my previous unacquaintance with the ordinary process, as also with the nature of the mucilage to be dealt with.

I found that if the whole of the mucilage was not got rid of, what was left immediately turned black by exposure to the atmosphere and very quickly got mouldy. All this of course you know, and I only mention it as an explanation of my failure in the object I had in view. But if the result of my experiments was unsatisfactory in one respect, it was satisfactory in another; it proved to me what you no doubt know, but which I did not, that fermentation of the beans is only practised for the purpose of removing the mucilage, that process being perfectly unnecessary for imparting the true chocolate color to the cocoa kernel, this being developed, in the course of drying the beans, by the conversion of the watery juices of the kernel into the colouring oil, which forms so large a portion of the cocoa bean. The satisfactory point ascertained by the experiments is, that not only may the whole of the mucilage be got rid of without any fermentation whatever, by a very simple and easy process, but the mucilage itself can easily be converted into a valuable product, instead of being wasted as by the present method.

I found by experiments that considerably more than half of the mucilage may be separated from the beans, by washing them, or rather mixing them, with a little water, and by agitating them in a revolving cylinder with perforated holes for the fresh saccharine liquor to run into a trough, which would convey it to a clarifier, which is the first process towards its manufacture into sugar.

That portion of the mucilage next to the beans—especially that adhering to them—is more refractory and difficult to separate, but I found that even this could be easily rubbed off by friction. I should think a machine, similar to a washing machine, would answer the purpose on a large scale. I may mention that in my small experiments a quantity of small stones was mixed with the beans to chafe them when revolving, sufficiently to remove the whole of the mucilage, and preserve it before fermentation set in.

If cocoa planters are indifferent to utilisation of the enormous quantity of saccharine contained in the mucilage, or think the result will not compensate for the trouble, I still think a much better and speedier way of getting rid of the mucilage may be hit upon than by the slow and wasteful process of fermentation. As a half or three-fourths of the mucilage can be removed at once by simple agitation, there is only the last coating to be dealt with—this could be rubbed off by some process or other. I obtained a beautiful sample of cocoa by rubbing the mucilage off with a rough towel. However, I have no intention of suggesting any particular way of removing it. I only wish to say that I think, for the reasons given above, that fermentation is a wasteful and an unnecessarily slow process. At present my interest in this portion of the question is very insignificant.

I will now advert to the point in the curing of cocoa, in which I am particularly interested, and that is, whether the principle of my tea-dryer cannot be applied to the drying of large quantities of cocoa (which, like the produce of its palm namesake, contains so large a quantity of oil as to render it very susceptible of mildew in a damp atmosphere) until the whole of the moisture is evaporated or dried out. I believe that my tea-dryer can be advantageously used for the purpose of drying cocoa in a manner which would not injure or remove the outer skin or parchment. The result of my experiments is to satisfy me that, in the first instance, the drying should be very, very gradual though continuous, to allow of the watery juices to evaporate gradually and for the colouring oil to take its place. If dried too quickly, the parchment will split on the germinating side; the watery juice will evaporate, and the kernel become dry before the oil has permeated the whole of the kernel; the result will be that some of them will dry white or mottled, and the parchment will crack in a way that will render it liable to become detached from the nibs in transport or manipulation.

My advice then is, if my dryer is used, to spread the cocoa fresh from the process of removing the mucilage on the hot surface rather thickly, say four or five inches thick, and keep it there until the whole becomes warm throughout. I would then remove it into bags, and let it stand for a few hours until a fresh charge is ready to be put into bags; I would then replace the first charge until it again became warm throughout; by thus alternating the charges, a large quantity of cocoa could be dried gradually, which I believe to be a necessity in cocoa curing. I assume that drying cocoa by artificial means would only be resorted to when it is impossible to dry it in the ordinary way—viz. by the heat of the sun, this method being obviously the cheapest one, though by no means the speediest, and during the greater part of the year the climate of the mountain zone of Ceylon renders it almost impossible to sundry cocoa satisfactorily on the estates. For the purpose of drying large quantities, a considerable area would be required. You can ascertain the cost by taking two and a-quarter rupees per superficial foot as the basis of calculation. The heat generated by the drying machines would, in a closed stove, with ventilators, hasten the drying of half-dried cocoa, and prevent mildew and discolouration.

In communicating the results of my crude experiments, I desire only to turn your thoughts into the channels I have indicated. I have not the materials for continuing the experiments, nor can I afford either to buy them or the appliances for doing so. You will, however, be able to continue them on the hints I have ventured to offer.—Yours truly,

C. SHAND.

P. S.—As the oil in cocoa beans liquifies at 120 degrees, the process of colouration is hastened by drying gradually on a surface heated to 170 degrees.

FORESTRY.

ANIMALS AND FOREST TREES.—A correspondent writing from Johnsonville, S. C., incidentally mentions a curious instance of the influence of animals in controlling or preventing forest growths. It appears that the fondness of hogs for the juicy roots of young pines leads them to seek them assiduously, so that where hogs are allowed to roam in that region, one can hardly find a young long-leaved pine in a thousand acres of pine forest. There being no young trees to take the place of the old ones used up by the lumbermen and turpentine gatherers, that species of pine timber is rapidly being exterminated.

FOREST TREE PLANTING.

THE planting of trees for ornament and shade, as wind-breaks, to preserve the natural area of forest, to ensure the best results from the cultivation of farm crops (not less than one-tenth of the area of a farm), or for the purposes of useful timber in prairie regions, is now admitted by all thinking men as among the indispensable industries connected with farm life. That forests do modify climates there is no longer doubt. That belts and clumps of trees largely mitigate the force of winds, and prevent the recurrence of those disastrous storms called blizzards, that periodically sweep over open districts of country, is capable of demonstration. That forests and groves hold the water of rains, giving it up slowly, is beyond cavil. That forests prevent the recurrence of our great river floods, however, is only true in a sense. The absence of forests do intensify floods. They rise faster

and decrease faster. Germany contains more forest area to-day through careful planting than it did 25 years ago. Yet it did not save that country from the great floods of 1863, the most severe on record.

The terrible flood of February in the Ohio, and consequent destruction of life and property, will long be remembered. That it was intensified in its suddenness is undoubtedly due to the cutting away of forests on the western slopes of the Alleghenies in New York, Pennsylvania, and West Virginia. This rise exceeded the great flood of 1832 and 1837 by only a few inches, but these few inches represent a vast surplusage of water as against medium and high water. It is idle, however, to say that the owners of mountain lands hundreds of miles away from the principal scenes of devastation, will be deterred from the cutting of timber thereby. It is present profits they are looking to, as are other men. The great forests are gone, but the great area is still covered with underbrush, as valuable as mature trees so far as covered areas are concerned. What the owners should be made to understand is that the planting of these slopes to valuable varieties of timber is the most economical use that can be made of such rough sections of country. This accomplished, the difficulty will be obviated and a fair preservation of timber will be secured.

Hoop poles are among the most necessary and valuable of young timber growths. A plantation made thick enough will in a very few years yield these by the natural thinning required. As the years pass, the subsequent thinnings are none the less valuable, as props to mines, that must be constantly renewed, posts, railway ties, &c., until at length the trees for mature growth will stand two or three rods apart as the case may be, and of just the varieties adapted to soil and situation. The difference between a piece of natural timber and a piece of planted timber lies in the fact that the natural timber contains far more timber of low value than of timber valuable in the mechanic arts. The planted timber is all valuable. Here is where the profit comes in, demonstrated beyond doubt in Europe and now capable of demonstration in this country. Let any farmer figure for himself. He will acknowledge that a grove will pay for planting in the protection it gives. Let him figure the actual value of such a plantation at 20 years of age, the trees averaging 12 inches through of black walnut, ash, catalpa, black cherry, larch, pine, spruce, or any of the valuable timber trees, standing 20 by 20 feet apart, or 108 to the acre, half of which may now be removed with advantage to the rest. It would amount to a large sum, and those left would be a sure source of income to his children if not to himself. It is not necessary to follow the matter farther. Any observing man may figure for himself that the profits are not less than in any of the other branches of common husbandry.

Let us now figure what to plant and how to plant. If simply for shade and roadside trees, elms, maples, and walnut among the slower-growing varieties, and cotton-wood, linden, catalpa among the faster growing varieties. For shelter of buildings and wind-breaks, Norway spruce is undoubtedly the best, though any of the evergreens may be used.

It is better to plant the seedlings of evergreens as grown by nurserymen for the purpose. The transportation is light and the seedlings may be thickly placed—one foot by three inches in the row. As they begin to crowd, take out every other plant, and again every other one in a row, and these will be all right for wind-breaks, &c., while the remaining plants now standing 12 inches apart, will be available for single trees to develop into their full beauty. The seed of deciduous trees should be planted pretty thickly in rows four feet apart as early in the spring as the soil may be worked. Nuts should be kept in moist, well drained sand during the winter, and if they freeze slightly they are none the worse. As they grow, thin out to about three inches in the row, transplanting to any weak places, and thin from year to year for planting out until the trees stand four by four feet. Here they will make nice trees for transplanting at the proper time, or for thinning out as required for poles, posts, &c. All small seeds as maple, linden, &c., should not be covered more than one and a-half inches. Nuts should be covered three inches, and these latter may be dropped in the row about three inches apart. All the nut trees should be planted where they are to grow, but with care in root pruning at one year old, they may be transplanted at two years. To plant large trees the holes are better made in the autumn. Then when the soil will work friably, dig them with as much earth as will adhere to the roots; do not allow the air to have contact with the roots more than can be avoided. Evergreens we have known killed by exposure to the sun or dry winds for a few minutes. When the tree is placed in the hole so that the collar will be little, if any, lower than—as it heretofore stood—the surface, throw in the finest soil, packing firmly about the fibrous roots; when the roots are well covered, press all firmly with the feet, being careful, however, not to scrape or bruise the roots. This firming is absolutely necessary. If the soil is dry, saturate with water, and cast over all where it has dried away the remainder of the earth, levelling all smooth, and stake if necessary.

Mr. Robert Douglas, of Waukegan, Ill., who certainly understands forest tree culture, in relation to planting forest trees over large areas, says:

"In order to establish the fact that forests can be successfully planted without the aid of experts, we took three contracts. Two of these plantations are in Crawford County, Kan. We have already planted 500 acres on these two contracts, and will plant 500 more acres before the first day of May next. These trees are planted by ordinary labourers, superintended by a man who never worked a day in a nursery. They are planted with spades, and stand four by four feet apart, the ground having been marked out the same as for corn. One man or boy holds trees for two planters, and the three together average 4,500 trees planted in a day of ten hours. We plant 2,750 trees to the acre; our contract calls for 2,000 trees; they stand over 2,500 to the acre."

They consist of three-fifths *Catalpa speciosa* and two-fifths *Ailanthus*. The catalpas three years planted stand from six to ten feet high and two to three inches in diameter at the collar, shading the ground so as to need no further cultivation. On the richest land they shade the ground after being two years planted. As these trees are planted by farm hands and cultivated with common corn cultivators, it proves that any farmer who can raise an acre of corn is competent to grow an acre of forest.

ARTIFICIAL PLANTING FOR PROTECTION.

D. JOHN A. WARDER, in a late number of the *American Journal of Forestry*, in an article detailing the work of planting certain portions of a large tract of land in Iowa, under the direction of Mr. Jesse W. Fell, well known for his efforts in tree-planting and tree culture, at Normal, Ill., concludes the article with some general remarks upon the effects of tree planting on climate, from which we extract the following interesting reading:—

"With a tract of land of even a few thousand acres thus planted and thus sheltered by trees to check the trying winds both of summer and winter, who that has once seen and realized the benefits of these wind-breaks will doubt the influence of trees upon the local climate, and their agency in producing and retaining the humidity of the atmosphere so essential to our crops and to our comfort or that of our cattle? Let such planting become general, and who can say that the climate of a whole region may not be measurably reclaimed from the aridity and severity that now prevails; and who will say in advance that such a covering of the surface, if carried on over still wider and more extensive regions, cannot and will not affect the average annual amount of rainfall? And yet, we are told, on high authority (Wm. Saunders, horticulturist, U. S. Department of Agriculture), that "to plant one hundred acres in trees, with the view of increasing the rain-fall on the adjoining one hundred acres of arable lands, seems to us a very weak proposition." Now, to many of us who have realized the benefit of wind-breaks on the prairies, it is no longer a weak but a very strong proposition, that judicious and extensive tree-planting does and must modify the local climate for our benefit, and that it might well affect the annual rain-fall. Time may be necessary to eliminate the possible errors arising from cycles dependent upon cosmical causes that are not yet fully understood; but let us have credit, and let the judicious plantations of trees have the credit for their influence in modifying the local climate of the farms, townships, counties, and states, where we do know that such ameliorating influences are sadly needed.—*The Garden*.

THE PURPOSE AND PROCESS OF GRAFTING.

IT is not difficult to understand the nature of grafting. A plant differs from an animal in several respects, and one of these differences is that a part of a plant can be separated from the rest, and, when placed under favorable conditions, will live and grow. If an arm or leg is cut from a man, or an ear or tail from a cow or horse, the part separated from the main body of the animal dies. The gardener well understands, and when he wishes to propagate the geraniums or verbenas, he separates small stems called cuttings from the large plant and sets them in moist sand, when the ends first callous and then send out roots into the moist mixture, and in a short time he has a supply of plants of the same variety as the one from which the slips or cuttings were taken.

In grafting the process is much the same, only a little more complicated, and therefore a trifle more difficult to do successfully. But by this it is not to be understood that the process is one requiring any great amount of learning. In grafting, a cutting of recent growth, called a cion, is shaped and fitted into a part of another plant called the stock. Instead of being put in the sand it is placed in the living substance of a plant, and derives nourishment for its growth from the stock. In order that this may be accomplished it is necessary that the growing layer of the cion and stock come close together. This growing layer, as it is termed, is situated just below the bark, at that point where the bark slips from the wood when a whistle is made of willow or other wood.

There are a number of important things to take into consideration in successful grafting. It is not enough to be able to set a cion and have it grow well, though that is very important. Grafting is done for the purpose of improving the tree or shrub thus treated, and therefore the quality of the cion should always be superior to that of the stock for the special end in view. For example, an apple tree may be all that could be desired in thrift, healthfulness, &c., but the fruit is of poor quality or small in quantity, or both. A superior sort is grafted upon such a tree and all the strength and vigor of the whole tree is used in making a good kind of fruit. Therefore, after deciding to graft a tree to improve it, one should be sure that the cions are of excellent quality. A tree may be made poorer by grafting as well as improved; in other words, there is no benefit to be derived in itself from the process of grafting.

The cions may be bought at most nurseries. If cut at home be sure that they are from well-known trees. Twigs of last season's growth only should be used. If more than one variety are used, tie up in bundles and keep separate with labels on each

package. The twigs thus cut should be put in moist sawdust or moss, and kept in a cool place until needed.

The implements needed in grafting are a fine saw for cutting off the limbs, a large knife and mallet for making the clefts, and a small, sharp knife, to be used in cutting the cions to proper shape. A wedge will also be needed for opening the cleft made in the sawed end of the stock. Grafting-wax, to protect the exposed surface from the weather, can be easily made from the three substances in the following proportions: Beeswax six ounces, rosin and tallow four ounces, melted together in a kettle, over a fire. Old cotton cloth, torn in strips, is waxed with this while melted and wound on sticks ready for use. This cloth is bound around the grafts after the cions have been set, care being exercised not to move the cions in the operation.

It has been stated above that it is not difficult to understand the nature of grafting, neither is it difficult to perform the operation. Any one with a small amount of that indescribable mental power called "gumption" can soon learn to graft. It is largely a matter of practice to do the work quickly and well, after the simple principles involved are once understood.

The time to graft is when the buds begin to swell. Having determined upon the place to graft, saw off the limb and, placing the large knife across the sawed end of the stock, strike it gently with the mallet, and thus make a cleft for the cion. With the small, sharp knife cut a piece from one of the twigs in the bundle so that it will bear two or three buds, shape the lower end into a wedge and insert this end into the cleft (opened by a knife) so that the growing layer will come against that of the stock and be bound there. This is the all-important point in grafting, and if not done the work is lost. If the branch is larger, bud grafts, one on each side, may be set. The after-work of grafting comes later in the season.—*CION*.—*Farmer's Review*.

THE GARDEN.

NOTES ON CULTIVATION OF RAINY-SEASON VEGETABLES.

MOST of the vegetables peculiar to the rainy season are rank growers, and require more room than the average sized garden can spare. Those not included are not of much value, and unless variety is an object, they may be safely left to the care of the native grower. If ever required, he will supply them as cheap as one can grow them.

Kheera (cucumber), *Cucumis sativus*.—The rainy-season varieties of this vegetable are very distinct from the variety with small egg-shaped fruit cultivated during the hot season. Two varieties are common in India, although, as far as flavour is concerned, there is little to choose between them. When in a young state the colour of one is a dark green, and of the other creamy-white. When full grown both are about a foot long, and the colour changes to a rusty brown. These two, although not equal to the commonest varieties met with in England, are not to be despised. They thrive with little care, and are always sure of yielding a crop. I annually try some of the English varieties, but have never been able to ripen a single fruit. They sometimes form, but invariably rot before attaining maturity.

In order to have them in use all through the season, three sowings should be made—the first in April, the second in May, and the third in June. Rich soil should be selected, and the seeds sown in lines five feet apart. When the young plants are about four inches high, supports should be given for them to climb on. The first sowing should be regularly watered, until the rains begin. Afterwards none need be given unless a break of more than ten days' duration should occur.

Kali Turai (*Luffa acutangula*); *Ohia Turai* (*Luffa aegyptica*).—These two vegetables require the same mode of cultivation, and may therefore be described together. When full grown, the fruit of the first-named is about a foot long, and of an angular shape. When out for use it should never exceed four inches in length. If cut when longer, it is quite useless for the table. The fruit of the second is about 6 inches long, dark green, and slightly spotted with creamy-white. It must also be cut when quite young.

Two sowings of both will keep up a supply from July until October. The first sowing should be made in April, and the second in the end of May or beginning of June. The seeds should be sown in lines at the same distance apart as cucumbers. The general treatment required is the same as described for the latter, and need not be again detailed.

Chachind (Snake-gourd); *Trichosanthus anguina*.—The fruit of this vegetable is from one to three feet long, and of a very handsome appearance. When young they are beautifully striped with white and green, and when ripe change to a brilliant orange. The young fruit is used as a substitute for French beans. When cut up into thin strips and boiled, they form a fair imitation of that vegetable. Like the *Kali* and *Ohia turai*, the fruit must be used when very young. If cut when more than 4 inches long; they often have a very bitter taste.

Two sowings should be made, the first in April, and the second in May. The distance apart and general treatment is also the same as described for cucumbers, and need not be again detailed.

Kurraili (*Momordica charantia*).—This, although botanically the same species, is a different variety from the one grown during the hot season. The natives of this district call the hot-season

variety *kurraila*, and the rainy-season one *kurraili*. The former variety does not require any supports to climb on, but the latter does. The fruit of both is much alike; however, the rainy season variety is, on the whole, smaller.

One sowing is enough to make of this vegetable. If this is done in the beginning of June, it will keep up a supply all through the rains. It also requires the same treatment as the cucumber.

Al Kudu (Laoki); Lagenaria vulgaris.—The fruit of this vegetable, if cut when quite young, is nearly equal to the vegetable marrow in flavour. Its size and shape varies very much. Some varieties are nearly a yard long, and others are compressed into short club-shaped gourds, not above a foot long. The flavour of all are nearly alike, and it is of little importance which variety one may possess.

It can be sown as early as February and as late as July. However, for rainy-season use, two sowings should be made, the first in April and the second in June. The first sowing will be ready for use in the beginning of the rains. The second will come in about the middle, and keep up the supply until the cold season. It can be sown in nurseries and transplanted, or sown at once where intended to be grown. The latter mode is preferable, but if an empty plot is not available when the sowing season arrives, it is better to adopt the first named, than let the sowing season slip past. It succeeds best in heavily manured sandy soil, but will thrive ordinarily well in any. When sown or transplanted, the seeds or plants should be inserted in patches 6 feet apart. No supports are required as it prefers to trail along the ground. It should be weeded when necessary, until the patches interlace and cover the ground. Afterwards it will not require to be touched, as the dense network of branches will keep down the weeds.

Kudu (Pumpkin); Cucurbita maxima.—There are several varieties common in gardens. The commonest one is a large globular gourd, and of a brown colour when ripe. If cut when about a pound in weight, their flavour resembles that of the vegetable marrow. It is also very good if used when full grown.

The seeds should be sown from April to June. It is a gross feeder, and requires very rich ground. The distance apart and general treatment is the same as described for *Al Kudu*, and it is needless to detail it over again.

Bhuta, Maka, (Indian-corn); Zea Mays.—The cultivation of this plant requires little care. There are numerous varieties in cultivation. It is a popular plant in America, and of late years that country has raised a large number of improved kinds. Although much superior to the varieties cultivated in this country, they cannot be depended on to produce a crop on the plains. For ordinary garden cultivation, and where a supply of corn-heads is the first consideration, it is better to grow the indigenous varieties, and leave the American kinds to the care of the experimentalist.

In order to have a supply of the green unripe heads of corn all through the season, it should be sown at intervals of a fortnight. The first sowing should be made about the middle of May, and the successive sowings continued up to the middle of July. The seeds should be sown in lines 15 inches apart, and 12 inches between each seed. When the plants are a foot high, they should be earthed up like potatoes. If the soil is rich and heavy, they will succeed very well without this being done, but if poor and light, the operation is very beneficial. It brings a greater supply of food within easy reach of the roots, and also lessens their chance of being blown over during storms.

Bhindi (Hibiscus esculentus).—This is a very wholesome, although not a palatable, vegetable to every one. The fruits, when cooked, are very slimy, and for this reason many do not care for it. Those who do not consider this an objection, find it palatable, and as it is easily managed, a few plants are not out of place in a garden.

It should be sown from April to June. One sowing is sufficient for keeping up a supply all through the rains. It should be sown in nurseries, and when three inches high, transplanted in lines two feet apart, and 18 inches between each plant. It will also succeed fairly well if sown at once in the plot where intended to be grown, but succeeds better if transplanted. It should be regularly weeded all through its period of growth. The oftener done the better, as frequent weedings keep the surface soil loose and open.

Lobia (Vigna catieng).—This is an annual plant with narrow pods from 6 to 12 inches long. It is one of the most useful of the bean tribe for rainy-season cultivation. There are many varieties of *arum (Dolichus)* cultivated during the rains, but as hardly any of them are ready for use until the cold season, I have excluded them from this paper.

This species should be sown just before the rains, and will be ready for use about the middle, and continue until the beginning of the cold season. The pods should be gathered when about six inches long. If gathered when longer they are tough and stringy. It should be sown in lines four feet apart, and treated in the same way as cucumbers.

—*The Indian Forester.*

W. G.

NOTES AND GLEANINGS.

NEW ROSES.—Among new roses shown by Messrs. Wm. Paul at the May meeting of the Royal Horticultural Society were four fine varieties named *Mlle. Marie Garnier*, deep rose; *Violette Bouyer*, blue; *Camoens*, fleshy crimson; and *Queen of Queens*, pale rose. All these had large and full flowers, except *Camoens*, which was remarkable only for its pretty colour. Mr. H. Beauquet, Shepperton showed a new hybrid tea rose named *Duchess of Albany*. It is large and full, of a pleasing soft pink hue.

POT ROSES.—On the above occasion also, a grand display of pot roses was made by Messrs. Wm. Paul and Sons, of Waltham-cross Nurseries. They consisted of about half-a-hundred well-grown plants, including some of the finest sorts, such as *Marie Baumann*, *Mlle. Marie Rady*, *François Michelon*, *La France*, *June* (a fine plant). The snowy whiteness of the fine blooms of *Mabel Morrison* contrasted beautifully with the rich deep velvety crimson of the superb *Duchess of Bedford*, a *Waltham Cross* rose, and one of the best of new roses of recent years. Among other roses raised by Messrs. Wm. Paul and Son were *Masterpieces*, bright rose-crimson; *Lady Sheffield*, a glowing cerise, the blooms large and fine in shape; *Star of Waltham* and *Little Gem*, a pretty new moss rose with compact rosette-like blooms of a rosy cerise. This group of pot roses was supplemented by half-a-dozen boxes of cut blooms equal in quality to those which one sees in July. Among them a large tray of about three dozen blooms of *Magna Charta*, showing that superb rose to perfection; noteworthy among the others were *Paul Verdier*, *Princess Marie Dolgorouky*, *Beauty of Waltham*, *Duke of Wellington*, *Crown Prince*, and *Dupuy Jamain*, all of which are excellent for early flower.

PYRETHRUMS.—From time to time we have mentioned pyrethrum as plants deserving the attention of colonial growers. One of the wild species is the source of the Persian insect powder, but hybridists have expended much skill and time in raising a race of double varieties, and they have succeeded in their task to perfection. At their meeting on May 9 the Royal Horticultural Society awarded the silver Bauksian medal to Messrs. Kelway and Sons, Langport, for a grand collection of these beautiful hardy flowers. "About 50 double kinds were shown, and about a score of single sorts. Among the latter there were some beautiful flowers, varying in colour from pure white through pink to the deepest crimson. A selection should include *Romulus*, *Deino*, *Themis*, *Rusticus*, *Melon*, *Damia*, *Dylis*, *Dacius*, and *Carbo*. A representative selection of the doubles are, among crimsons and pinks, *J. N. Twerdy*, *Sefton*, *Nemesis*, *Progress*, *Gloire d'Italie*, *Hobart Pasha*, *Duchess of Edinburgh*, and *Captain Nares*; and among light-coloured kinds, *Niveau*, *plenum*, *Album roseum*, *Mont Blanc*, *Vance*, *Cleopatra*, and *Solfaterra*."

LAPAGERIAS.—These finest of greenhouse climbing plants are to some extent exceptional in their requirements. If grown in houses where any warmth is used further than is sufficient to keep out frost they are excited to earlier growth, and under such circumstances I have found the young shoots and leaves very impatient of exposure to the full force of the sun, which not unusually has the effect of stopping the shoots from attaining their full growth, and causing the leaves to be deformed. Any aspect seems to suit these plants better than the south, yet if in too dark a position they rarely flower, however strong they may be, so freely as when more favourably placed in this respect. Now, whilst the young growth is in its tenderest condition, a thin shade of some kind should be applied and the soil should be kept well moistened, especially if the plants are grown in pots or tubs, and the roots fully occupy the soil; but where small or medium sized examples have been recently turned out in beds of considerable extent the earth must not be made too wet, otherwise it will get into a soddened condition, under which the plants do not thrive. Syringe every afternoon, getting the water if possible well to the under sides of the leaves; if this is attended to regularly, thrips, to which these plants are so subject, will be kept down, an essential point, for though the hard texture of the leaves prevents their being killed outright, still the insects feeding on them shorten their duration—a sad mishap when used for covering back walls and similar places in conservatories, for which purpose lapagerias are well adapted.

LILACS.—The varieties of these are numerous, but only about half of the number that have been named can lay claim to distinctness, the shades of colour, the chief distinguishing character in many of the kinds, being remarkably alike. The majority belong to the common lilac (*Syringa vulgaris*), and it is a remarkable fact that there are comparatively few varieties of the Persian lilac (*S. persica*). One of the very finest varieties in flower is called *Prince Camille de Rohan*, a kind which stands out prominently from all the rest on account of its dense panicles of blossom, which in the bud stage are a deep rosy-crimson, but lighter in the expanded state. A similar, but not such a fine, sort is one called *Sinensis rubra*, and next in merit is *Professor E. Stockart*. *Rosea grandiflora* is a very fine variety, which has exceptionally fine panicles, lighter in colour than those of either of the kinds named, but very pleasing. The foregoing comprise some of the most distinct of the dark-coloured varieties. Among those that are but little different from the type of *S. vulgaris* are those named *Goliath*, *purpurea*, *rubra*, *cerulea*, and *media*. The major variety, called also *Charles the Tenth*, is well known. It is an excellent kind for forcing, and should be included among the best of the dark varieties, as should also the double flowered sort, which possesses the advantage of remaining in flower longer than the rest. The best of the pure whites is *Ville de Troyes*, which is much superior to the common white (*S. vulgaris alba*), having larger flowers and denser panicles. Another, called *Jacques Callot*, is but little different from *Ville de Troyes*. The most noteworthy varieties of the Persian lilac are the white (*alba*), now becoming a scarce plant, even in the best nurseries, and the cut-leaved variety (*laciniata*), an elegant shrub called also *pteridifolia*. The *Rouen* lilac (*S. rothamagensis*) is an extremely pretty shrub that deserves to be better known than it is. It differs from the Persian in being neater and more compact in growth, and in having narrower leaves. We found it here under its synonym *S. dubia*. There are a few varieties of it, the white (*alba*) *sanguinea* and *Gloire de Moulins* being the most remarkable. Among other distinct species *S. Jotkma*, a Hungarian lilac, will shortly be in bloom, and later on the Himalayan *S. Emodi*, also very distinct from any of the commoner lilacs.—*The Garden*.

SERICULTURE.

A CORRESPONDENCE writer :—"The extension of *sericulture* in North India is not yet to be despaired of. It is true that natives here know nothing about the industry. It is probable that no European has yet proved that it can be made successful commercially. But considering the very inexpensive nature of the process of rearing the cocoon, that it can be done by women and children, and that the worm is indigenous to the province, it is certainly possible that the industry may be developed. In the Hoshiarpore experiments, the best plan of rearing the worm was found to be to put it out when very young on the *beri* tree in the open, and there to guard its natural enemies—crows, sparrows, and, worst of all, wasps. In order that the trees on which worms are put may be properly watched, they must be kept of a moderate size, and planted close together. The watching can be done by children. Sometimes more than a hundred cocoons have been taken off one small *beri* tree. The worms strip the tree of its leaves, but a young *beri* will send forth a second crop of leaves the same season. The rearing of the worm could then be conducted with almost no expense to the cottager. But it involves the trouble of careful watching, and the moths have to be caged to ensure a supply of eggs. The conditions of successful rearing have been approximately, but not fully, gauged. A large number of cocoons are annually reared in the jungles by the wild tribes in Central India and some parts of Bengal. Did Major Consmaker try rearing in the open, on trees of moderate size planted together? It would be interesting to see details of his experiments."

SERICULTURE IN NEW ZEALAND.

MR. WILLIAM COCHRAN, writing to a contemporary regarding the suitability of New Zealand for silk farming, has the following :—"Passing over the unanimous verdict of the Press in favour of silk farming as likely to form a pleasant and remunerative employment for women and children, besides helping to add materially to many a cottager's income during periods of commercial depression, I come to a paragraph which must be quoted intact :—"In the United States, for the introduction of new and valuable industries, or the development of any which already have a footing, there is a lively public spirit, and as a consequence thereof the promotion of such enterprises is part of the business of Government. A special department of State is devoted to the purpose, and anybody wishing to embark in this line or proffering suggestions or co-operation is not snubbed as an enthusiast, but can rely on getting full and practical information for his guidance, and State aid also when necessary and proper."

The great importance and value of the silkworm eggs trade forms a feature of which the Colonial Press takes due note, amounting, as it does, in the case of Japan, to three million sterling per annum. It is argued that as no disease of any kind has yet appeared in the province of Canterbury among the worms, as last year's harvest extended from September 1881 to June 1882, and as the white mulberry grows with great luxuriance notwithstanding late and sharp frosts, the sericulturists there should confine their efforts mainly to egg production. As an illustration of the happy effect that climate exercises on imported eggs, it is mentioned that cocoons, moths, and silk lately raised from *graine* brought from Japan and Victoria admitted of no comparison with the foreign article. The New Zealand-bred cocoon, to use the language of the Colonial newspaper, "is heavier, firmer, and by a great deal larger than either of the others; the New Zealand moth looks capable of swallowing the little Victorian moth and asking for more; while the Australian and Japanese silk is far behind ours in strength, evenness, and gloss." The *Press* of Canterbury, on January 20th, notices "some very beautiful specimens of raw silk prepared from cocoons, obtained this season."

The samples are intended to be forwarded by the Governor to England, with the view of testing practically the capabilities of New Zealand as a silk-growing country. At the end of March, Mr. Federil intends to send home in the refrigerating chamber of the S.S. *British King* some *graine* to London, for the purpose of distribution in France and Italy, to test the health of the worms raised in this country."

It is stated that it requires 500 acres of cultivable land, or 5,000 acres of bush land, to produce in wool as much value as can be extracted from one acre of mulberries in the form of silk; and it should be remembered that almost on the threshold of the industry in New Zealand the cropping season, even in a frost-visited province like Canterbury, has already been prolonged to nine months, as against the three months originally calculated upon, or the six weeks of Europe and Asia. It seems to me that those facts ought to dispose of the charge of exaggeration and blind enthusiasm brought against the advocates of sericulture in New Zealand on more than one occasion by thoughtless persons in this country and elsewhere, and by one illustrious statesman in the Colony. It has been already indicated in my former letter that it is desired to promote a public company, with a capital of at least 150,000*l.*, to purchase a tract of land: for this purpose an eligible estate of under 10,000 acres has been offered at a reasonable price and on easy terms. The land is situated on the Bay of Islands within three miles of the rising town of Russell, which promises to be, at perhaps no very distant date, the future first port of call in New Zealand for the steamers of the Pacific Mail Company arriving from New South Wales and San Francisco. The estate possesses a frontage to the bay of about two miles; is bounded for about nine miles by a picturesque, tree-fringed river, fordable in only three places along that distance; and the land is intersected by several smaller streams, this promising abundance of water-power.

Such a desirable estate as this is described to be and so evidently suited for the purpose indicated, should not be allowed to revert to ordinary agricultural purposes without careful inspection by a qualified commissioner, and an attempt made to effect its purchase if found all it is paluted. If these and former remarks recommend themselves to enterprising capitalists throughout the Empire, the period has evidently arrived when energetic and speedy measures should be adopted. The New Zealand Government is ceasing to be lethargic over this matter, and doubtless an influential public company once formed would necessarily command that prompt attention to its suggestions or proposals which an obscure individual need hardly expect.

NATURAL COLOURED SILK.

THE prevalent colour of the raw silk that meets the eye of the visitor to the London Docks is yellow; but there are other natural tints known, and the number might be considerably increased were the teachings of careful observation better learned and digested. Thus, we already receive pure white silk in its greatest beauty from Palestine; an almost colourless variety from the *baroo poloo* worm; nearly white silk from the *mezankooroo* insect; and a delicate grey filament from the *atlas* grub—all belonging to India. China, Japan, Persia, and Sicily export mainly the golden-yellow variety, and India a similar colour in quantity in addition to those just alluded to. To these may be added the beautiful fawn-tinted silk of Northern China, obtained from a gigantic worm which feeds upon the leaves of the mountain oak, but will not refuse those of the mulberry when offered; and the pearl-grey produce of the *Attacus Cynthia*, fed upon the leaves of the ailanthus, and now successfully reared both in France and parts of England. If we eliminate the pure white and grey (which can scarcely be regarded as colours) from this list, yellow in various shades is really the only decided hue at present possessed by the raw silk of commerce. With the knowledge of the numerous successful experiments in the direction of obtaining other colours in a natural manner conducted some years ago, it may well be asked if the present paucity is altogether creditable to the sericulturists of the period. In 1876 M. Roulin obtained pale blue cocoons by slightly dosing his silkworms with indigo, carefully mixed with their mulberry-leaf food, shortly before they began to spin. The leaves of the *Bygonia chica*, or trumpet-flower, of the river Orinoco—belonging to an order yielding the most gorgeous climbers yet met with in the world—enabled him to feed his worms so as to obtain beautiful red cocoons; and, doubtless, his investigations have since been rewarded by the production of further natural decided colours. About the same time another clever sericulturist, Hulmet des Tallies, discovered that a magnificent red tinge could be communicated to cocoons by feeding the silkworms for a time on a variety of vine, and a deep emerald hue by the use of lettuce leaves.

It is quite likely, of course, that the long-continued silkworm maladies of Europe may have interrupted those interesting and eminently important experiments, and the circumstance may be accepted as an excuse for tardiness in following them to a practical issue. But it is at the same time gratifying to learn that our countrymen who are about to introduce tea and silk-farming as a combined industry into New Zealand intend to prosecute this line of research with assiduity, as the splendid evergreen flora of those islands gives promise of unusual facilities for experiment, and points to the probability of a grand result.

TOBACCO.

THE total area under tobacco at the Ghazipore tobacco farm has, we observe from a report of the Agricultural Department in the N.-W. P. and Oudh, risen from 404 acres in 1880-81 to 482 acres in the year 1881-82, and the produce from 270,000lb to 326,000lb. The rate of produce per acre was for both years 675lb per acre. Of the entire produce of 326,000lb, 61,000lb were shipped to England, 60,000lb were manufactured into smoking tobacco for the Indian market, and 10,000lb were made up into cheroots, 2,800lb into cigarettes. The shipment to England realised 5d. per pound, and the prices realised in India were about 6 annas per pound for cavendish and one rupee for smoking mixture, 8 annas for cheroots, and 2 rupees for cigarettes. It is proposed, we see, to extend the area under cultivation, when a still better rate of produce is expected.

SEEDING TOBACCO BEDS.

MARCH and April are the months for making the tobacco bed or plant patch. At the South some of the planters make the bed in the fall, and we have known such cases here in the valley. Usually the bed is selected in the fall, fertilized or ploughed, or spaded in, then left until spring. When wanted for sowing, the bed is first spaded deep and all turf stone, bits of grass and rubbish of all kinds thrown away. In fact, the object is to make the bed as mellow as it can well be. The bed is now carefully raked, and made even, and rounding so that the water will run to either side. The bed may now be trod hard before sowing; some omit this, until after the seed is sown.

In regard to the seed, whether wet or dry seed was sown; if dry, it should have been put in pan half full of dry sand so that the seed will not come up in bunches, which makes the bed look bad. If wet seed is to be sown, take mould from about an old tree. This mould should be quite moist; sift it, and mix thoroughly the seed and mould together. Put it under the stove, cover with a cloth so that it will not get too hot. If the seed is good, in 48 hours white specks will appear. That is the germ of the tobacco seedling. They should not grow too fast or too long, since they may be broken off in sowing.

The seed may now be sown by the handful (small) or by what one can hold between the fingers. As the mould is usually darker in color than the tobacco bed, one can tell whether he has sowed the bed even or not. Make, however, more than one bed; sometimes it fails to come. They may be poor, or, for some cause or other, we have no plants.

We have been describing the process of making tobacco beds in Connecticut, and the method of making and sowing the seed is the same the world over. Most growers sow too much seed so that a good deal of pulling out is required. Havana and Yara plants do not require as much room in the bed as seedling plants, since they grow up like cabbage seedlings. In a few days the young plants will appear in the tobacco bed and in ten to twelve, if the bed is full of weeds, the work of getting them out will come in order. We prefer a damp to a dry piece of ground for this and many reasons. The seedlings, if kept moderately damp, are more apt to germinate than when sown on dry ground where they take up but little moisture, unless the watering-pot is kept a-going most of the time.

After the first weeding, which should be done well, sprinkle the bed with plaster, and let the bed go until 12 or 15 days more; by this time the seedlings ought to be quite large, the largest leaves the size of a silver dollar. From this time forward until "settling," the beds are tended in various ways, the weeds pulled out, the small ones rejected, old trodden plants on the border thrown away, and, if necessary, the bed given a weak solution of Peruvian guano water. But don't give the seedlings too strong a dose, else they may be injured and destroyed outright.

In New England and the Middle States transplanting occurs from the 25th of May to 20th of June, but plants are "set out" as late as the 4th of July. Havana plants are bad to "set" since their roots are long like a cabbage. Of seed leaf from 5,000 to 6,000 plants are set to the acre; of Havana, 6,000 to 7,000, according to the seed. We sow seed six or seven years in descent from the imported. A fine crop of Yara tobacco was sold here late at 16 cents. It produced about 700 pounds to the acre, at least the two acres brought \$400, so the grower said. Grow good tobacco, and it is a profitable product. It is in demand now the world over.—B.—*Farmers' Review*.

GOVERNMENT

CINCHONA FEBRIFUGA.

A N efficient substitute for Quinine. Sold by the principal European and Native Druggists of Calcutta. Obtainable from the Superintendent, Botanical Gardens, Calcutta. Post free, at 40s., Rs. 6; 8oz., Rs. 11; 16 oz., Rs. 20-18. Cash with order.

PLANTERS' STORES & AGENCY CO., LIMITED,

MERCHANTS AND GENERAL AGENTS,

Calcutta,—30, STRAND.

General Manager—W. E. S. JEFFERSON.

Manager—

Agencies for Tea Estates undertaken on the most advantageous terms.

Coolies recruited by our own staff of experienced Agents, with Depôts throughout Chota Nagpur and at Dhubri.

Indentors and Consignees of all merchandise.

Army, Navy, Civil Service, and Private Agents.

Assam.—"THE EXCHANGE," DIBRUGARH.

W. J. WHEATLEY, Manager.

A. D. STUART, Agency Superintendent.

Direct Importers of every requisite for Tea Estates and European Residents.

Price Lists on application.

Agents for India General Steam Navigation Co., Ltd.; Agents for Commercial Union Assurance Co., Fire and Life;

Agents for "Star" Line Ocean Steamers,

Calcutta to London; Agents for

Reuter's Telegram Co.,

Limited.

London.—GREAT WINCHESTER-STREET, F.C.

E. G. Rook, Secretary.

Agencies at Birmingham, Bordeaux, and Charente.

6

FRANCE.

CONTINENTAL & COLONIAL AGENCY

(LICENSED),

14, RUE DE CHABROL, PARIS.

Transacts every description of Commission, Merchant, and General Agency Business.

All Indents executed at Manufacturers' most favourable terms.

Conditions.—Two and a-half per cent. Commission when Banker's Draft on London or Paris accompanies order. Special terms to regular correspondents. All Discounts conceded to purchasers, Original Invoices sent when required.

Produce taken charge of and realised to best advantage. Cash advanced on Consignments.

The Agency Represents, Buys, and Sells for Firms.

Public Securities, Estates and Properties, bought and sold, Loans, Mortgages, Mines, and Industrial Investments, &c., negotiated.

Manufacturers and Producers can have suitable articles introduced to the markets on advantageous conditions.

PRICE LIST—comprehensive and reliable—on application.

BANKERS.—PARIS: George Waters, Esq., 30, Boulevard des Italiens. LONDON: The London and County Bank, 3, Victoria-street, Westminster.

Address: The Manager, Continental and Colonial Agency, 14, Rue de Chabrol, Paris, France.

THE GREAT REMEDY FOR PRICKLY HEAT, INDIGESTION, HEADACHE, BILIOUSNESS, AND FEVERS.

The testimony of medical gentlemen has been unqualified in praise of

LAMPLOUGH'S PYRETIC SALINE,

As possessing elements most essential for the restoration and maintenance of health with perfect vigour of body and mind.

It is Effervescent and Tasteless; forming a most Invigorating, Vitalising, and Refreshing Beverage.

Gives instant relief in HEADACHE, SEA or BILIOUS SICKNESS, CONSTIPATION, INDIGESTION, LASSITUDE, HEARTBURN, and FEVERISH COLDS; prevents and quickly cures the worst forms of TYPHUS, HOARSENESS, JUNGLE, and other FEVERS, SMALLPOX, MEASLES, and ERUPTIVE or SKIN COMPLAINTS, and various other

Dr. FROST.—"Unfading source of immense benefit to mankind."
Dr. MORGAN.—"It furnishes the blood with its lost saline constituents."

Dr. BEARDS (Government Medical Inspector of Emigrants from the Port of London) writes:—"I have great pleasure in bearing my cordial testimony to its efficacy."

GOVERNMENT OFFICIALS AND PLANTERS caring for the welfare of their employees should note its value as a specific in Fever cases.

Dr. J. W. DOWLING.—"I used it in the treatment of forty-two cases of Yellow Fever, and am happy to say I never lost a single case."
Dr. W. LEVY.—"Since the introduction of the Fatal West India Fevers are deprived of their victims."

Dr. H. J. BROWN, REPRESENTATIVE OF THE GOVERNOR OF SIERRA LEONE, in a letter of request for an additional supply of the Pyretic Saline, states:—"It is of great value, and I shall rejoice to have it in the houses of all Europeans visiting the tropics."

Dr. RAWLY, SIMONE, FUMJAU, INDIA.—"We firmly believe that the use of your Pyretic Saline will do more to prevent fever than all the Quinine ever imported can cure."
Dr. TROLEY.—"I found it act as a specific, in my experience and family, in the worst forms of Scarlet Fever, no other medicine being required."

Dr. S. GIBSON (formerly Physician to the London Hospital).—"Its usefulness in the treatment of disease has long been confirmed by medical experience."

To be obtained of any Chemist or Drug Store, in Patent Glass-stoppered Bottles, 2s. 6d., 4s. 6d., 11s., and 21s. each. Please note in connection with the recently observed effects of the use of Citrate and other preparations of Magnesia that LAMPLOUGH'S PYRETIC SALINE is warranted not to contain any substance which would cause calculous or other earthy deposits.

H. LAMPLOUGH, 113, HOLBORN HILL, LONDON, E.C.

ZULULAND AND CETEWAYO.

"I know what it is," he answered; "this honey is made from euphorbia flowers, which are very poisonous." This explanation made me feel exceedingly uncomfortable; but I elicited from him that there was not much danger, as the 'maas' taken with it would neutralise the effect of the poison. Directly he mentioned poison I dived into the packs, and pulled out a bottle of ENO'S FRUIT SALT, and emptying a quantity into two pannikins, filled them up with water, and several times repeating the dose, in a few hours we were considerably better."—*"Zululand and Cetewayo," (p. 139), by Captain W. R. Ludlow, 1st Batt. R.V. Royal Warwickshire Regiment.*

"What on earth shall I take to Zululand?" asked my friend Jim Law one day at Aidershot, when he had just received orders for South Africa, to start at forty-eight hours' notice. I replied, 'If you take my advice—and it's that of an old traveller—you'll not budge without a few bottles of ENO, even if you leave half your kit behind. I never am without these Salts, and, please the pigs, never intend to be.' On his return I inquired, 'Well, how about ENO'S FRUIT SALT?' 'My dear fellow, it was the best advice you ever gave; they saved me many an illness; and when I left Tuogla, I sold the remaining bottles for ten times the original price!'—*Lieut.-Col.*

JEOPARDY OF LIFE. THE GREAT DANGER OF DELAY.

You can change the trickling stream, but not the raging torrent.

WHAT EVERYBODY SHOULD READ.—How important it is to every individual to have at hand some simple, effective, and palatable remedy, such as ENO'S FRUIT SALT, to check disease at the outset! For this is the time. With very little trouble you can change the course of the trickling mountain stream, but not the rolling river. It will defy all your tiny efforts. I feel I cannot sufficiently impress this important information upon all Householders, or Ship Captains, or Europeans generally, who are visiting or residing in any hot or foreign climate. Whenever a change is contemplated, likely to disturb the condition of health, let ENO'S FRUIT SALT be your companion; for, under any circumstances, its use is beneficial and never can do harm. When you feel out of sorts, yet unable to say why, frequently without any warning you are suddenly seized with lassitude, disinclination for bodily or mental exertion, loss of appetite, sickness, pain in the forehead, dull aching of back and limbs, coldness of the surface, and often shivering, &c., &c.; then your whole body is out of order, the spirit of danger has been kindled, but you do not know where it may end: it is a real necessity to have a simple remedy at hand that will answer the very best end, with a positive assurance of doing good in every case and in no case any harm. The pilot can so steer and direct as to bring the ship into safety, but he cannot quell the raging storm. The common idea when not feeling well is, "I will wait and see, perhaps I shall be better to-morrow;" whereas, had a supply of ENO'S FRUIT SALT been at hand, and use made of it at the onset, all calamitous results might have been avoided. What dashes to the earth so many hopes, breaks so many sweet alliances, blasts so many auspicious enterprises, as untimely death?

ENO'S FRUIT SALT.—"After suffering for nearly two and a half years from severe headache and disordered stomach, and after trying almost everything and spending much money without finding any benefit, I was recommended by a friend to try ENO'S FRUIT SALT, and before I had finished one bottle I found it doing me a great deal of good, and now I am restored to my usual health; and others I know that have tried it have not enjoyed such good health for years.—Yours most truly, ROBT. HUMPHREY, Post Office, Barrasford."

SUCCESS IN LIFE.—"A new invention is brought before the public, and commands success. A score of abominable imitations are immediately introduced by the unscrupulous who, in copying the original closely enough to deceive the public, and yet not so exactly as to infringe upon legal rights, exercise an ingenuity that, employed in an original channel, could not fall to secure reputation and profit."—**ADAMS.**

CAUTION.—Legal rights are protected in every civilised country. Examine each Bottle, and see the capsule is marked "ENO'S FRUIT SALT." Without it you have been imposed on by worthless imitations. Sold by all Chemists, price 2s. 9d., and 4s. 6d.

THE ART OF CONQUEST IS LOST WITHOUT THE ART OF EATING.—DINNER ENGAGEMENTS.—STIMULANTS.—TOO RICH FOOD.—LATE HOURS.—INSUFFICIENT EXERCISE.—EXCITEMENT, &c., &c.—A gentleman writes: "When I feel out of sorts, I take a dose of ENO'S FRUIT SALT one hour before dinner or first thing in the morning. The effect is all I could wish." How to enjoy good food that would otherwise cause biliousness, headache, or disordered stomach—use ENO'S FRUIT SALT.

DIRECTIONS IN SIXTEEN LANGUAGES HOW TO PREVENT DISEASE.

Prepared only at ENO'S FRUIT SALT WORKS, HATCHAM, LONDON, S.E., by J. O. ENO'S Patent.

PHOENIX IRON WORKS, CALCUTTA.

THE OLDEST ENGINEERING ESTABLISHMENT IN INDIA, JESSOP & CO.,

**Civil and Mechanical Engineers, Contractors, Brass and Iron Founders,
Metal Merchants, &c.**

*Forged and Cast Iron Work, Boilers, Machinery for Jute, Cotton and Rice Mills, Collieries, Indigo Concerns, Tea Gardens, &c.,
Contractors' and Brick-making Plant, and every class of Iron and Brass Work made to order.*

SOLE AGENTS FOR

Robey & Co's celebrated Portable and Fixed Engines and Machinery, Gwynne & Co's "Invincible" Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

IMPORTERS AND MANUFACTURERS OF EVERY DESCRIPTION OF STEAM ENGINES AND MACHINERY.

Robey & Co's Portable, Horizontal, Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand, Lift and Force Pumps, Tangye's "Special" Steam Pumps, "Vauxhall"

Donkey Pumps, Flour Mills, Soorkee Mills, Pug Mills, Brick-making Machines, Road Rollers, Saw Benches,

Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and

Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines,

Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selkirk's Boiler

Tube Benders, Steam Pressure Recorders, Electric Pens,

Richard's Engine Indicator, Gifford's In-

jectors, Cooking Stoves, Fire-

Proof Safes.

The following are the principal advantages of the "Invincible" Pump :—

1st.—It is arranged to swivel on the bed plate, and may be placed at any angle simply by slackening a few nuts, without interfering in any way with the bed plate or the joints of either the suction or discharge pipes.

2nd.—It does not require a foot valve, being fitted with small air exhauster and clack on discharge which always keep the pump charged ready for work.

3rd.—The bearings are made on an entirely new principle, and one bearing will last out four of the old arrangements.

**J. & H. GWYNNE'S
"Invincible" Centrifugal Pump.**

4th.—The form of the pump casing is so arranged that one side can be taken off in a few minutes for the inspection of the whole of the disc and interior of the pump.

5th.—Hand holes are made on each side of the suction pipes to enable any foreign matter which may get into the pump or disc to be easily removed. The covers are fitted with a bayonet joint so that they can be removed and replaced in less than a minute.

6th.—The "Invincible" is 25 per cent lighter than any other Centrifugal Pump in the market, and discharges at least 10 per cent. more water for the power applied.

Ransome's Indian Plough. Price, Rs. 15.

Howard's Ryots' Plough. Price, Rs. 20.

These Ploughs have been expressly designed and manufactured for the use of the Ryots of India, whose special needs have been carefully studied in their construction. They embody all the qualifications for which the native-made implements have hitherto been preferred, whilst being incomparably superior in strength, durability, and efficiency.

MORAE'S PATENT SUB-SOIL AND GENERAL PLOUGH

Stirs up the soil to three times the depth of a native plough, and leaves the good mould on the top. Goes through the dirtiest land without getting choked with weeds. Price, Rs. 15.

INDIGO AND TEA PLANTERS' IMPLEMENTS AND STORES.

ENGINEERS' TOOLS AND STORES OF ALL KINDS.

ALWAYS ON HAND A LARGE STOCK OF PLATE, BAR, ANGLE, TEE AND CORRUGATED IRON, STEEL, BRASS, COPPER, PIG IRON, FOUNDRY COKE, SMITHY COAL, FIRE BRICKS, AND FIRE CLAY.

 Catalogues on Application.

GOODALL'S Household Specialities.

A Single Trial solicited from those who have not yet tried these Splendid Preparations.

YORKSHIRE RELISH.

The Most Delicious Sauce in the World.

This cheap and excellent Sauce makes the plainest viands palatable, and the daintiest dishes more delicious. With Chops, Steaks, Fish, &c., it is incomparable. In bottles, at 6d., 1s., and 2s. each.

GOODALL'S BAKING POWDER.

The Best in the World.

Makes delicious pudding without eggs, pastry without butter, and beautiful light bread without yeast. In 1d. packets, 6d., 1s., 2s., and 5s. tins.

GOODALL'S QUININE WINE.

The Best and most Agreeable Tonic yet introduced.

The best remedy known for Indigestion, Loss of Appetite, General Debility, &c. Restores delicate individuals to health. At 1s. 1d. and 2s. 3d. each bottle.

GOODALL'S CUSTARD POWDER.

For making Delicious Custards without Eggs, in less time and at half the price.

The Proprietors can recommend it to Housekeepers generally as a useful agent in the preparation of a good custard. Give it a TRIAL. Sold in boxes, 6d. and 1s. each.

GOODALL'S GINGER BEER POWDER

Makes Three Gallons of the Best Ginger Beer in the World for Threepence.

The most valuable preparation for the production of a delicious and invigorating beverage. It is easily made, and is by far the cheapest and best Ginger Beer ever offered to the public. Sold in packets, 3d. and 6d. each.

GOODALL'S EGG POWDER.

Its action in Cakes, Raddings, &c., &c., resembles that of the egg in every particular. One penny packet will go as far as four eggs; and one sixpenny tin as far as twenty-eight. Sold everywhere, in 1d. packets; 6d. and 1s. tins.

GOODALL'S BLANCMANGE POWDER

Makes delicious Blancmange in a few minutes. In boxes at 6d. and 1s. each.

All the above-named Preparations may be had of all Grocers, Chemists, Patent Medicine Dealers, and Oilmen.

Proprietors: GOODALL, BACKHOUSE & CO, Leeds, England.

FREEMAN'S SYRUP OF PHOSPHORUS.

Nature's Great Brain and Nerve Tonic and the most wonderful Blood Purifier. The highest Medical Authorities say that it is the only Cure for Wasting Diseases, Mental Depression, Loss of Energy, and Stomach Complaints.

It is pleasant to the taste, and might be taken by the most delicately constituted. In the most enfeebled it builds up a NEW AND HEALTHY CONSTITUTION. One dose of this Remedy is equal to Twenty Doses of Cod-Liver Oil.

Thousands have been snatched from the brink of the grave by the timely use of FREEMAN'S SYRUP OF PHOSPHORUS. May be had of all Chemists and Patent Medicine Vendors, in bottles at 2s. 6d., 4s. 6d., 11s., and 15s.

SUTTON'S SEEDS & CATALOGUES

MAY BE HAD OF DULY AUTHORISED AGENTS

IN EVERY PART of the WORLD,

INCLUDING—

The Proprietors, *Indian Agriculturist*, Chowringhee-road, Calcutta; the Great Eastern Hotel, Company, Limited, Calcutta; Messrs. Wilson, Mackenzie & Co., 13, Old Court House-street, and 1, Mangoe-lane, Calcutta. Orders received by Messrs. King, Hamilton & Co., Calcutta.

NOTICE.

[In ordering through London Shippers, purchasers should be particular to stipulate for SUTTON'S SEEDS.]

TESTIMONIAL.

From S. Jennings, Esq., late Vice-President of the Agri. Hort. Society of India.

"With reference to your mode of packing seeds for export, I must say how much I was gratified with the system you were so good as to show me. During the whole of my long Indian experience, it was my constant regret that English packed seeds were almost invariably lower in germinating power than the American. After seeing the elaborate precautions you take in executing such orders as that of the Agri-Hort. Society of India, I am by no means surprised to hear that you have been gratified by the receipt of so much testimony from the tropics as to the condition of your Seeds upon arrival."

S. OWENS & CO.,

WHITEFRIAR'S-STREET, LONDON,
HYDRAULIC ENGINEERS AND MANUFACTURERS OF
PUMPING MACHINERY OF EVERY DESCRIPTION
FOR STEAM, WATER, WIND, CATTLE, AND MANUAL POWER.

Hydraulic and Screw Presses, Oil Mill Machinery, Hydraulic Lifts, &c.

SOLE MAKERS FOR GREAT BRITAIN OF

BLAKE'S PATENT DIRECT-ACTING STEAM-PUMP,—MORE THAN 10,000 IN USE.

THE FOLLOWING ARE SOME OF THE PROMINENT ADVANTAGES OF THE BLAKE PUMP:—

It will start at any point of stroke.
It has no dead point.
It works fast or slow with the same certainty of action.
It is economical. Has a lead on the Slide Valve.
It is compact and durable.

Hand Power Lever Detached.

It is intact in all its working parts. It will deliver more water than any other Pump. It is made of best materials in the most workman-like manner.
Can be worked at 200 strokes per hour, or 20 strokes per minute.

BLAKE'S PATENT
Direct-Acting Steam Pump and Boiler Feeder.

Oil Mills, for Steam or Cattle Power.

Double-barrel Contrabore Pumps, for Hand or Steam Power.

Double-barrel Fire Engines, for Mansions, Factories, &c.

Deep-well Pump, for Hand Power.

Deep-well Pumps, for Horse or Bullock Power.

Vertical Combined Steam Engine, Boiler, and Deep-well Pumps.

Fire Engines, for Towns, Railway Stations, &c.

Force Pumps on Barrow.

Wrought-iron Portable Pumps.

Patent Centrifugal Pumps, for Condensators use, or Irrigation Work.

Cast-iron Horse or Garden Pump.

Portable Irrigators for Horse or Steam Power.

Double-barrel Force Pumps in Frame.

Improved Steam Boring Apparatus, also

BORING TOOLS.

Boring Tools of every description, for Artesian Wells, testing for Minerals, Foundations, &c.

BLAKE'S PATENT DIRECT-ACTING STEAM PUMP AND VERTICAL BOILER
FOR IRRIGATION PURPOSES,
FILLING TANKS, WATER-SUPPLY TO PLANTATIONS, SMALL TOWNS OR VILLAGES.

Whitefriar's Ironworks, Whitefriar's-street, Fleet-street, London.

Catalogues and Estimates Free on Application.

THE INDIAN AGRICULTURIST.

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. VIII.] CALCUTTA:—FRIDAY, JUNE 1, 1882.

[No. 6.

GANDY'S PATENT COTTON BELTING.

SPECIALLY SUITED FOR AND PATENTED IN INDIA AND ABROAD.

PRIZES.

OVER 450,000 FEET SOLD DURING 1881,

Including 3,877 feet of main Driving Belts, of widths ranging from 13 in. to 60 in., are working in over 6,000 Mills and Works in Europe and America.

The following Tests (by Kirkaldy, of London) show the relative strength and value, compared with Leather.

| | Breaking strain per Square inch of section. | Price per foot. |
|-----------------------------------|---|-----------------|
| Best Double Leather 6 in. Belting | 3,572 lbs. | 8s. 7d. |
| Gandy's 6 in. x 2-ply Cotton | 6,811 lbs. | 2s. 6d. |

THE GANDY BELT.

Any Length or Width
for Main Driving.

It is the best belt ever made for all purposes. Much Cheaper and Stronger than Leather. Thoroughly Waterproof, and not affected by temperature, oils well to the pulleys, runs true, and can be made any length without joints.

This Series of Belting (see engraving) was supplied in One Order to Messrs. John Crossley and Sons, Halifax, May 1, 1880, and continues to give entire satisfaction.

MAURICE

A SUBSTANTIAL GUARANTEE GIVEN WITH EVERY MAIN DRIVING BELT.

Patentes and Manufacturer,
190, Queen Victoria-street,

LONDON,

WORKS Liverpool, England;
and Baltimore,

U.S.A.

These tests are given above, to which special attention is to be given, by having two belts on the same pulley, a system of driving which is never satisfactory, by of exactly the same tension; hence one or the other is always causing a stoppage. ed by using Gandy's Patent Belts in one width. These Gandy Belts are made of the finest specially prepared at Baltimore for the purpose, and then put together and finished by Gandy's try and process to prevent stretching, and render them impervious to atmospheric influence. Moreover, the universal adoption of Gandy's Belts can only be a question of time.

City Line of Steamers.

FOR LONDON DIRECT via SUEZ CANAL.

HEALTH, STRENGTH, AND ENERGY.

DR. LALOR'S PHOSPHODYNE.

(Trade Mark—Phosphodyne.)

TWENTY YEARS' PUBLIC TEST, AND THOUSANDS OF TESTIMONIALS FROM

ALL PARTS OF THE WORLD ESTABLISH

PHOSPHODYNE

as the only Safe, Reliable, and Never-failing Phosphoric Remedy for Over-worked Brain, Sleeplessness, Harassing Dreams, Worry, Anxiety, Excitement, Epilepsy, Business Pressure, Wasting Diseases, Nervous Prostration, Stomach and Liver Complaints, Impoverished Blood, Premature Decay, and all morbid conditions of the system dependent upon the deficiency of the Vital Forces.

DR. LALOR'S PHOSPHODYNE PURIFIER AND

Enriches the Blood, Clears the Skin, thoroughly Invigorates the Brain, Nerves and Muscles, Re-energises the Failing Functions of Life by supplying the PHOSPHORIC element which has been wasted, and thus imparts Energy and Fresh Vitality to the Exhausted Nerve-Electric Force, and rapidly Cures every form of Nervous Debility, Paralysis, Kidney, Nervous, Mind, and Heart Diseases, from whatever cause.

This elegant Phosphatic combination, the Wonder of Modern Chemistry, is pronounced by the most eminent members of the Medical Profession to be unequalled for its power in replenishing and elaborating the Vitality of the Body; by its supplying all the essential and vitalising constituents of the BLOOD, BRAIN, and NERVE SUBSTANCE; and for developing all the Powers and Functions of the System to the highest degree; by its being agreeable to the palate, and innocent in its action. While retaining its wonderful properties, it acts as a Specific, surpassing all the known THERAPEUTIC AGENTS of the PRESENT AGE, for the SPEEDY and PERMANENT CURE of the above disease.

DR. LALOR'S PHOSPHODYNE is sold in Bottles at 4s. 6d. and 11s. by all Export, Wholesale, and Retail Medicine Vendors throughout the World.

IMPORTANT NOTICE.—NONE IS GENUINE UNLESS the name, Dr. Lalor's Phosphodyne, London, England, is blown in the Glass of each Bottle, and every Bottle bears the British Government Stamp, with the words DR. LALOR'S PHOSPHODYNE, London, England, engraved thereon by Order of her Majesty's Honourable Commissioners; IF NOT, IT IS A FORGERY, AND YOU HAVE BEEN IMPOSED UPON BY A WORTHLESS IMITATION.

MANUFACTURED ONLY AT THE

PHOSPHODYNE LABORATORY BY

DR. ROBERT D. LALOR,

BAY HOUSE, 32, GAISFORD-STREET, LONDON, N. W.

(THE SOLE PROPRIETOR AND ORIGINATOR OF PHOSPHODYNE.)

PHOENIX IRON WORKS, CALCUTTA.

THE OLDEST ENGINEERING ESTABLISHMENT IN INDIA,
JESSOP & CO.,

Civil and Mechanical Engineers, Contractors, Brass and Iron Founders,
Metal Merchants, &c.

*Forged and Cast Iron Work, Boilers, Machinery for Jute, Cotton and Rice Mills, Collieries, Indigo Concerns, Tea Gardens, &c.,
Contractors' and Brick-making Plant, and every class of Iron and Brass Work made to order.*

SOLE AGENTS FOR

Robey & Co's celebrated Portable and Fixed Engines and Machinery, Gwynne & Co's "Invincible" Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

IMPORTERS AND MANUFACTURERS OF EVERY DESCRIPTION OF STEAM ENGINES AND MACHINERY.

Robey & Co's Portable, Horizontal, Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand, Lift and Force Pumps, Taugye's "Special" Steam Pumps, "Vauxhall" Donkey Pumps, Flour Mills, Soorkee Mills, Pug Mills, Brick-making Machines, Road Rollers, Saw Benches, Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines, Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selkirk's Boiler Tube Benders, Steam Pressure Recorders, Electric Pens, Richard's Engine Indicator, Gifford's Injectors, Cooking Stoves, Fire-Proof Safes.

The following are the principal advantages of the "Invincible" Pump:—

1st.—It is arranged to swivel on the bed plate, and may be placed at any angle simply by slackening a few nuts, without interfering in any way with the bed plate or the joints of either the suction or discharge pipes.

2nd.—It does not require a foot valve, being fitted with small air exhauster and clack on discharge which always keep the pump charged ready for work.

3rd.—The bearings are made on an entirely new principle, and one bearing will last out four of the old arrangements.

J. & H. GWYNNE'S
"Invincible" Centrifugal Pump.

4th.—The form of the pump casing is so arranged that one side can be taken off in a few minutes for the inspection of the whole of the disc and interior of the pump.

5th.—Hand holes are made on each side of the suction pipes to enable any foreign matter which may get into the pump or disc to be easily removed. The covers are fitted with a bayonet joint so that they can be removed and replaced in less than a minute.

6th.—The "Invincible" is 25 per cent lighter than any other Centrifugal Pump in the market, and discharges at least 10 per cent more water for the power applied.

Ransome's Indian Plough. Price, Rs. 15.

Howard's Ryots' Plough. Price, Rs. 20.

These Ploughs have been expressly designed and manufactured for the use of the Ryots of India, whose special needs have been carefully studied in their construction. They embody all the qualifications for which the native-made implements have hitherto been preferred, whilst being incomparably superior in strength, durability, and efficiency.

MORAE'S PATENT SUB-SOIL AND GENERAL PLOUGH

Stirs up the soil to three times the depth of a native plough, and leaves the good mould on the top. Goes through the hardest land without getting choked with weeds. Price, Rs. 16.

INDIGO AND TEA PLANTERS' IMPLEMENTS AND STORES.

ENGINEERS' TOOLS AND STORES OF ALL KINDS.

ALWAYS ON HAND A LARGE STOCK OF PLATE, BAR, ANGLE, TEA AND CORRUGATED IRON, STEEL, BRASS, COPPER, PIG IRON, FOUNDRY COKE, SMITHY COAL, FIRE BRICKS, AND FIRE CLAY.

 Catalogues on Application.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah in particular varies so much in the different provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

CARBOLIC ACID AND HEMILEIA.

TO THE EDITOR.

SIR,—In your issue of the 1st May you refer, in an article on *Hemileia*, the coffee-leaf disease, to the measures that have been recommended for the mitigation of the ravages of that pest, and you say "prominently the process of Storek appropriated by Schrottky."

Surely there is a misprint in this; the names ought to be reversed. For in January, 1881, I recommended, as the result of my experiments, the application of carbolic acid acting as vapour as one of the best means for checking the spread of the disease. The process was tried with some measure of success at several coffee estates in Ceylon during the same month, and public attention was drawn to them in the *Ceylon Observer* and *Ceylon Times*.

It was not for several months afterwards that we first heard of Mr. Storek working in the same direction in Fiji, and recommending a similar process.

EUGENE C. SCHROTTKY.

Mozufforpore, May 21, 1883.

NOTE.—In the year 1871 the fumes of carbolic acid were used in Ceylon on the estates of the Uva Coffee Co., Ltd., and Springvalley Coffee Co., Ltd. We are not alone in believing that Mr. Schrottky was, to put it mildly, considerably behind others in parading carbolic acid fumes. Mr. Storek, in the columns of the *Ceylon Observer*, claimed the process as his. We invite Mr. Schrottky to settle his little difference with Mr. Storek.—ED., I. A.

THE SUPPLY OF FOOD-STUFF FOR LIVESTOCK, AND VEGETABLE FUEL, IN YEARS OF DROUGHT AND SCARCITY.

TO THE EDITOR,

SIR,—The causes of short or inadequate supply of food for the live-stock and fuel for burning are mainly the following:—(1) the distances of centres of consumption from localities where they are produced; (2) the unremunerative character of these supplies which prevent the populace from producing them; (3) the treacherous character of Indian rainfall; (4) the paucity of agri-horticultural produce of the country which prevents the live-stock from receiving their share of food; (5) the enormous consumption of wood for the railways; (6) the rapid increase of population which use wood fuel for cooking and sundry manufactures; (7) the want of adequate knowledge of growing such kinds of plants, agri-, horti-, and arbori-cultural, which possess high value as fodder or

fuel, hence unsuited plants badly grown result in unremunerativeness which, after a single failure, are given up by the growers as no purchasers would care to purchase them.

1. In small rural villages, the number of live-stock, in ordinary years, is very small: the villagers always try to carry their surplus produce to such centres of consumption and trade where they may find ready sale of their produce at remunerative prices. The carriage adopted by them is their heads, and the backs of their plough or any other cattle, ponies and asses (rarely). Carts are used, but very limitedly, owing to the extreme badness of the internal district roads, which are entirely *kacha*, and rendered uncommunicable for heavy cart-loads by the travelling of foot passengers and that of animals of all kinds during summer and winter seasons; and during the rains these roads are the "slough of despond" to carts of any description, large or small, heavily loaded or otherwise; because the wheels stick fast into the mud and cannot be extricated unless the carts are unloaded and much labour and time wasted, for their stock in trade having much bulk and weight and little value. From what I have said it will appear that carriage of fodder and fuel from rural places is by very costly means to the distant centres of consumption; but the prices offered for these commodities are very small, which prevent the villagers from carrying these articles for sale. The subject to be here dealt with is whether sufficient fodder is produced for the cultivators' cattle, and whether any surplus is left for live-stock of other people who do not produce food but buy and feed.

An ordinary *ryot* of India, as a rule, cultivates 5 acres of *rubbee* (winter crop) and 5 acres of *khareef* (rainy-weather crop.) The minimum produce of these 10 acres, only one crop in a year to a given area, is as follows:—

| | |
|---|--------------------------------------|
| <i>Rubbee</i> .—5 acres of wheat, barley, or any other Grain. | Straw. |
| cereal or pulse crop at 10 mds., of Mds. Mds. Mds. | grain, and 20 maunds of straw, per |
| acre | 50 + 100 = 150 |
| <i>Khareef</i> .—5 acres of maize, millet or any other | fodder yielding crop at 20 maunds of |
| grain or seed, and 50 maunds of stalk, | per acre |
| | ... 100 + 250 = 350 |
| Total produce | 150 + 350 = 500 |

For the cultivation of these 10 acres, in two seasons, the cultivator has two pairs of bullocks or 4 animals. These receive an allowance of 10 seers of chaff or stalk (*bhoosa* or *katya*, II.) each daily during the summer and winter; in the rains they are allowed to graze and receive no stall feeding. So that the nine months' stall feeding represents a whole year's feeding for these 4 animals is $(10 \times 4) \times (30 \times 9) = 270$ maunds, which subtracted from 350 (fodder produce) = 80 maunds surplus of straw reduced to chaff and dried stalk available for sale to non-producers of fodder who rear live-stock. The feeding allowance is the maximum because the *ryot* effects economy in feeding by mixing grass, oil-cake, &c., with the chaff or chopped stalk, thus enabling him to save and store fodder for some months longer for the ensuing year. My daily allowance to a milch cow of the *Jamnuparee* breed (large size) was only 5 seers of chaff and oil-cake, and cabbage and turnips. If the *ryot* be a good cultivator, he can certainly double or even quadruple his grain and fodder produce. The above estimate (a very close one) refers to the most ordinary unskilled *ryot*.

Here there are two causes,—distance and want of proper road communication which obstruct the free circulation of fodder and fuel—animals of one quarter starving and those of the other having more than wanted; so also there is plenty of fuel in one quarter and in another none at all, or a very inadequate supply.

2. Indian cultivators do not raise fodder and fuel plants separately. These substances are derived from produce obtained which were grown for other objects. For instance, the wheat plant is raised for its grain which serves as food for man, also for animals if given, and its straw serves as provender for the live-stock; the same might be said of trees which are grown for fruit, gum, bark, timber, and in rare cases flowers and leaves, and the branches serving as fuel. But nowhere will an Indian cultivator grow, as in the civilized countries, and as the primary object, any plant as food for live-stock or for fuel. The reason is no remunerative market will be found for fodder or for fuel if plants are exclusively raised for each of these two purposes. In the existing state of the Indian markets, therefore, if loss is suffered by the cultivators for these articles, they have other parts of the plants to fall back upon for profit. These facts and impressions are so strong in the

minds of the cultivators that nothing short of well established profit will induce them to grow plants specially for fodder or for fuel.

3. The paucity, uncertainty, and in rare instances total cessation of rainfall are the main causes which have induced the Government of India to take in hand the very laudable object of supplying food for live-stock of all kinds and fuel for cooking food, the railways, and for manufactures.

4. The consumption of vegetable fuel by the railways is daily becoming so very extensive that unless immediate measures be adopted for keeping up the continuity of wood supply, it is not possible to meet the demand—the supply must fail. No statistics of the quantity of wood the State and other Railways consume in firing their engines, and in smelting, shaping, manufacturing, &c., in their workshops, per diem, have been gathered; and it is not known how much wood they annually burn. These require to be known to arrive at the data on which to base the estimate of area to be under fuel-supplying plants. It should be borne in mind that wood fuel demand by the railways, unless coal takes its place, will continue to increase as new railway lines go on opening and to be opened.

5. The demand for wood fuel for cooking food is daily increasing by the increase of human population of India. It is said the average of human population of India is 300,000,000 which number multiplied by 8, the average number of pounds of fuel burnt daily per head, gives the large quantity of 2,400,000,000 lb. = 1,250,000 tons of wood burnt daily in India, and the last number $\times 365$ (the number of days in the year) = 456,250,000 tons of fuel consumption for cooking food per annum. The above figures should be taken as approximate average of annual fuel consumption of India for cooking food only; and it includes fuel burnt on festive occasions and sweetmeat and other edible manufactures. It is not known what quantity of wood the mills and manufacturing engineering establishments, &c., use for their engines, smeltings, bollings, &c., no statistics having been gathered. Charcoal being the compound carbonaceous residuum of wood, obtained by artificial means, is included in wood.

The approximate estimate of wood consumption under this paragraph, plus that of para. 4, will give the total fuel requirements for the whole of India. In computing for the area to be under fuel-supplying plants, maximum should be taken.

The inference of the whole described above is that the landholders and the cultivators having failed to achieve the objects which lead to the prosperity of the country, the Government of India proceeds to supply fodder and fuel, apart of other wants, which is very good indeed. I should surmise the proviso equally require to be extended to all parts of India under the sway of the British Government of India, and not confined to small tracts of the country which have shown symptoms of collapse; because the paucity of fuel is very greatly felt in Oudh, Bengal, and other provinces where trees are fast disappearing to supply wood for burning.

It will not be out of place here to suggest that the reserves for fodder and fuel should be as close as possible to the centres of consumption, viz., large villages, towns, and cities, and with due regard to good road communications, existing or to be constructed.

By right of conquest the British Government of India has full rights to appropriate any area, and of any situation of land without any payment. But the Government of India promises to pay *reasonable price* for the land it will appropriate, which shows how great a condescension and leniency it has towards its subjects.

INDIGO PLANTING.

TO THE EDITOR.

SIR,—I have been some time in search of a work on indigo planting and manufacture, but have not been able to find one. Will any of your numerous subscribers be kind enough to give me the name of such a work, and from where it can be procured?

ENQUIRER.

The Indian Agriculturist.

CALCUTTA, JUNE 1, 1883.

PLANT DISEASES.

IN our last issue we endeavoured to show that the origin of disease in plants was due to an excess of hyper-organised matter, notably albuminoids, consequent on the reckless administration of certain fertilisers. The chemical composition of mildew fungus in a manner supports this assumption. Two specimens of mildew generated from solutions of sugar and gelatin, and sugar and ammonium chloride, analysed by N. Sieber, (J. pr. chem. (2) 23, 412-421) gave respectively the following results :—

| I. | | | II | |
|--------------------------------|-----|-----|--------|--------|
| Substance soluble in ether ... | ... | ... | 18.70 | 11.10 |
| " " " alcohol ... | ... | ... | 6.87 | 3.36 |
| Ash ... | ... | ... | 4.89 | 0.73 |
| Albumen ... | ... | ... | 29.88 | 28.95 |
| Cellulose ... | ... | ... | 39.66 | 55.77 |
| Total | | | 100.00 | 100.00 |

The substance soluble in alcohol and ether was crystalline, but its composition was not determined. We have however in the one mixture, or soil, producing the mildew, gelatin, and in the other, ammonium chloride, substances both of which will yield nitrogen on decomposition. From the plant albuminoids therefore it may with strong reason be inferred that mildew, such as the *hemileia* springs. There can be but little doubt that this pest, and others, such as the *Tylenchus Havensteinii* found by Kühn in lucerne and red clover, the *cephus pygmeus*, and *C. troglodytes* found by Brummer in rye straw, and which is the cause of its blanching; the contagious fungi, *tilletia*, *caries* (stinking smut), and *t. calvis* of wheat, the *tilletia maydis* of maize, the *plasmiodiphora brassicae* of cabbage, the *agaricus melleus* of the mulberry, and the *phytophthora infestans* and *saprophyte* of the potato, are of like composition and like origin. The phytophthora and saprophyte are presumably the direct effects of fermentation, for Reinke and Berthold have found in phytophthora infested potatoes, bacteria, *bacillus subtilis*, and *bacterium necrotica*. Potatoes having a maximum of starch resist the disease most energetically, while those grown on moist soil containing much organic matter, such as stable manure, are most liable to attack. The reduction of the amount of sugar in the roots of the vine when attacked by phylloxera points also to a like internal disturbance as being the cause of mildew appearing on the roots. In the case of the vine, however, the fermentation may be induced by some diastatic body, or it may be the result of hydration. The sugar (saccharose) appearing in the stalks of some plants is considered to be a direct product of the elaboration of chlorophyll. Glucose is in most cases not found unaccompanied by saccherose; it is therefore a product of the hydration of the latter. When therefore there is an excess of chlorophyll-forming substance in the soil, i. e., organic nitrogenous matters, saccherose may be changed to glucose, which, under certain conditions, will ferment and yield fungi, harmless perhaps at first, but which might blend with other germs, and after several transitions give rise to fungi of a virulent type.

Diastatic fermentation in plants may with propriety be ascribed to an excess of albuminoids, and the fact that diseased vine leaves contain more nitrogen than the healthy leaves renders it probable that phylloxera may have originally been the result of diastatic disturbance: at any rate, the fungoid diseases of the vine may with strong reason be ascribed to this cause. The fact that the seeds of the vine, which resist the attacks of phylloxera, are stronger and more regularly formed, points either to a draining of the sap by this pest, or to a fermentative disturbance following exhaustion. The vine, like coffee, is a

huge feeder on potash, but it is questionable whether it gets this either in the shape or quantity required. In this connection it has been proved that clover sickness and the disease of the horse chestnut are due to the want of this element in the soil, and that they are remedied by its introduction—thus incontestably proving that clover sickness cannot be due to the parasites proper found thereon. We therefore with reason argue that phylloxera is due to a like want. Lime, it is understood, is as necessary to young plants as it is to young children, but we do not recognise this necessity—that is, generally speaking, for had we half attended to the wants of plants in this respect, many a plague familiar to us to-day would have been unheard of. A judicious use of it now will, we venture to predict, greatly modify existing plagues, and avert others.

In all solutions containing bacteria, says Wernich, "a time arrives when they cease to propagate, and after a longer time, they lose their power to induce further life in fresh nutritive solutions." From this fact it is argued that the putrefaction induced by bacteria produces substances which are poisonous to these organisms. Some such reaction may take place when hemileia is at a low ebb, and its re-appearance may be due to the development of new bacteria. If this be so, it remains for us only to withdraw and withhold from the soil material conducive to fresh development, if we wish to render extinction permanent. Bacteria have been found in air drawn from the soil; whether, however, they find their way into plants and communicate disease direct is doubtful. It is more reasonable, knowing that putrefaction may be either a diastatic or a purely hydratic change, to suppose that they result in the usual way from the putrefaction of albuminoids, and that by the succeeding fermentation peculiar to their presence, substances are developed which are deadly to themselves. Indeed, experiment proves that substances most disposed to putrefaction may be preserved from it by means of phenol, skatole, and indole—products of putrefaction. "These experiments," says a commentator on Wernich's views, "lead to the solution of a highly interesting problem in pathology." And the author himself says that the same or similar operations are carried out in the progress of septic diseases, and that the supposition that the organisms which are the cause of infectious diseases, give rise to products which eventually cause their own extinction, is the only way in which the progress of these diseases can be properly comprehended. Here the idea of inoculation occurs, which, with respect to coffee plants, has already been worked on, but not completely. If we admit, however, that in the reactions attending the appearance of hemileia, and other fungoid growths, their own distinctive antidotes are produced, we would still have to withhold from the soil the essentials to fresh growth before any such disease could "burn itself out." We therefore repeat, and we cannot be too clear on this point, that the use of these antidotes externally, or even by inoculation, will avail us nothing while the conditions necessary to fresh growth remain. Given, we say, the conditions necessary to fermentation proper, hydration, or putrefaction in the plant, and we have not far to seek for the origin of diseases. We have in hyper-organised sap a ready nidus for disease spores from without, and all the conditions for their actual evolution within. Agriculturists up to the present time have taken a certain interest in chemistry, the atmosphere, and the weather, in the food of plants and their value; they have noticed the occurrence of disease, and the peculiarities of its recurrence; they have been always ready to try any nostrum forced upon their attention; and still foster the vain delusion that these plagues will be removed by God, or that some genius will discover the remedies approved by grace. The custom of attributing these visitations to God is weak and puerile in the extreme. The fault is with ourselves. We neglect to study the physiology of the plants we cultivate, and when by haphazard means we fail to remove the evils attending this neglect, we come to the conclusion that the Great Geometrician of the Universe has suspended locally, or checked, what we may appropriately term the great fundamental law of nature—vegetable growth. If we admit this assumption, surely coffee-planters and growers of the vine are a peculiarly wicked people. The mere fact that these diseases vary in intensity with the alternation of the

seasons; that, like the plants which constitute the soil in which they flourish, they are subjected to precisely similar laws, with regard to climate and temperature—is indicative of their origin, and not only points to the truth of Wernich's remarks about each producing its own antidote, but to the means for making the effects of such permanent; and that they are no more indications of Divine anger than are common weeds. It is true that we do not as yet know the precise causes of the bulk of the diseases casually alluded to, but knowing the causes which have conjointly conduced to their development, it is in our power to extirpate them. That this end may be easily attained we incline to believe, even in the absence of unanimity, but in cases of this kind, unless unanimity is guaranteed, *individuals* will not work; they will naturally argue that, when they have banished the disease from their own possessions, it may again be communicated from without. We are firmly convinced that were the essentials to hyper-organisation withdrawn and withheld from an area of soil, no such recurrence would result; but we are unable to say whether and how far we are right, so long as we are deficient in a clear and definite understanding of the penetrating power of atmospheric disease germs on healthy plants. We are certain, however, that such could not originate within healthy plants. We would, therefore, for ourselves adopt measures for the restoration of a healthy state of things, without fear of suffering from the apathy of our contemporaries. We can well imagine that we would be alone in this respect, or nearly so, but one such example would be sufficient to show the wisdom or folly of our argument. The whole question seems to us very simple. These diseases grow, ripen and cease. They grow again and ripen and cease: consequently it seems logical to aim at stopping their growth, and folly to simply kill them before their time. In the one case we attack the cause, and in the other the effect. We are far from saying that it is hyper-organisation of the sap is due directly to neglect, for we know that certain esculents suffer from a sudden fall of temperature, and we have seen coffee at high altitudes suffer from the same cause: the epidermis cells become ruptured, and the circulation of the sap is impeded, and this effect alone could, we know, result in fungoid disease, and be followed by parasitic attacks. This susceptibility, however, of the plant to suffer from cold is in most cases we think, due to some defect in the soil: to the want of some essential in the plant; therefore, consider them as we may, we are instinctively led back to the belief that hyper-organisation, if not the direct cause, is the primary effect of that cause, and the effect from which all bad results spring.

THE CAWNPORE EXPERIMENTAL FARM REPORT FOR THE KHARIF SEASON, 1882.

NITROGEN, it seems, is still the element to conjure with and swear by at Cawnpore. Mr. Fuller has been translated to the happy hunting-grounds of the Central Provinces, and Major Pilcher planted in his stead in the nitrogenous deficient soil of the Cawnpore Experimental Farm. Major Pilcher, the soldier, has beaten his sword into a lot of ploughshares, and his other implements of war are exchanged for crucibles, retorts, re-agents, soluble phosphates, bone dust, and other interesting substances. We have no knowledge whatever of Major Pilcher. He may be the most suitable man in all India for the position he has been placed in at Cawnpore; but this square-man-round-hole business of placing soldiers and warrior judge, in charge of Experimental Farms seems to us about as wise as placing ploughmen and pig-drivers in command of regiments, and giving district and divisional commands to growers of big cabbages, superlative turnips, and gigantic gooseberries. The Cawnpore Farm may want nitrogen, but it has now got a Major. May we hope that the presence of the one will counterbalance the absence of the other? Major Pilcher, however, is probably better known, at all events in Lucknow, as a Small Cause Court Judge, than as either soldier or an agriculturist. On the authority of Mr. Bennett, the Director of Agriculture of the North-West Provinces, Major Pilcher has also a practical knowledge of

chemistry. On the whole, what more does Cawnpore want? Let it solace itself for its want of nitrogen. It seems to us that Major Pilcher, with all his varied experiences and acquirements, speaks with a lesser power of assertion in his report than the Director of Agriculture does in the resolution on the report. "As far as they go," says Mr. Bennett, "the trials of various kinds of manure confirm the main results of previous years, and point to nitrogen as the element in which the soil of the farm is deficient. On four standard plots the average produce given by nitrogenous manures was 2,138 lbs. per acre, while that given by phosphates and manures not rich in nitrogen only averaged 1,337 lbs. On the duplicate plots the averages were 1,686 lbs. and 1,014 lbs., respectively. The increase in outturn was 60 per cent in the first case, and nearly 70 per cent in the second."

Major Pilcher, on the other hand, while recording the superiority of yield from nitrogenous manures, says, with becoming caution, that little is to be learned from experiments which have little continuity.

"Nitrogenous manures," we are quoting Major Pilcher, "as may be seen, maintain a very marked superiority in yield as against manures yielding little nitrogen; and the duplicate plots corroborated fairly the results of the standard plots save in the case of the saltpetre standard plot, which shows a variation due probably to unexhausted poudrette. There is little to be learnt, however, from experiments which have as yet so little continuity; and patience must be exercised until a sufficient number of annual experiments have been carried out to enable us to assert positively that, by a certain expenditure on any particular manure, corresponding increase in produce can be obtained, returning a fair profit on such expenditure."

The truth appears to us to be that in India, where officials are changed about from "pillar to post," continuity in agricultural experiments seems impossible; and even were continuity of experiments insisted on by the Government of each province, and officials of the Agricultural Department appointed to work out certain experiments under the natural variations common enough year by year in rainfall, sunshine, heat, wind, and all else that make up climate, the initial difficulty in our estimation would be to get men capable of conducting such experiments, and deducing general results from them. The power of observation and experiments is not by any means so common as most people believe; in fact, so uncommon is it that when a man really capable of accurate observation and exhaustive experiment does appear, he takes the very highest rank in those subjects he has devoted himself to. Of all the fields of knowledge in which men have sought to bind the forces of nature to the chariot wheels of science, probably none are so difficult and intricate, with constantly changing conditions and unexpected results, that baffle all chance of eliminating as the experimental study of agriculture. It requires no Indian Experimental Farms to prove that the application of certain manures under certain conditions results in a heavier and better paid crop. It is possible to produce the most astonishing results if crops are treated in small patches, horticultural rather than agricultural, and it seems to us that there has been a tendency in certain quarters to give agricultural experiments a horticultural twist. At all events, experiments are conducted at Experimental Farms under conditions that place the reproduction of them by the ordinary ryot entirely out of the range of possibility. The changing of officers breaks the continuity of experiment, even supposing they were capable of conducting experiments that would result in something more than mere commonplace, or the reproduction of the ill-digested opinions and assertions of pretentious men.

Perhaps the most interesting part of the report is that devoted to the attempt to manufacture sugar from the sorghum plant. The advantages which sorghum possesses are, "that it can apparently be grown as an ordinary *khari* crop on poor land, year after year, without irrigation, and does not require the great labour, expense, and capital requisite for sugarcane. It only occupies the ground four months, and can be grown in places where sugarcane cannot be grown at all. If too poor a crop for sugar, it is still a most nutritious fodder for cattle, the seed being also good food. If fine enough for sugar, it keeps the mills going for a month earlier. Cattle eat the *magans* greedily, while they will not eat that of sugarcane. The leaves

and tops also go to the cattle. From fermented juice alcohol can be distilled, and from the skimmings of the boiling-pan, vinegar can be manufactured. Sorghum may therefore be said to have potentialities.

The following is what is said regarding sorghum sugar in the report under notice :—“ The attempts of last year to manufacture sugar from sorghum were renewed this year and with better success. Two fields were sown.

(1) “ Was divided into three sections, which were respectively planted with Minnesota early amber, acclimatised red sorghum, and acclimatised black sorghum. The field was manured with farmyard manure at 100 maunds to the acre.

(2) “ An unmanured plot in which sorghum was planted for cattle-food.

“ Contrary to expectation, the unmanured plot gave a better crop than the manured plot. This may have arisen from the fact that No. (1) lies lower than No. (2), and was waterlogged for some time in July. In America the general opinion is in favour of a sandy upland soil well drained, but not freshly manured. A professional sugar-boiler (kindly procured for the farm by Messrs Thomson and Mylne) could make nothing out of the juice at first, and pronounced it impracticable. One of the farm apprentices, accustomed to sugar-boiling, then tried his hand on it, and by the use of lime succeeded at last in making *goor* of fairly good quality from the early amber and the red varieties, but for a long time failed with the black variety : eventually succeeding with that also by adding a very small quantity of carbonate of soda, as well as lime, to the boiling juice.

“ Samples were sent to Carew and Co., Limited, to Messrs. Thomson and Mylne, and to the Agr. Horticultural Society, Bengal. A sample was also submitted through a native gentleman to a committee of sugar-brokers in Lucknow, the manner and place of its production being carefully concealed. The following opinions were received :—

Messrs. CAREW AND CO.

“ I have now the pleasure to send analysis of your sample of sorghum, and to remark—

“ 1st.—It is very acid. Having no experience of sorghum juice, I do not know how far this is due to delay or accident in manufacture.

“ 2nd.—The amount of glucose is large and is probably due to the acid, which has the effect of converting crystallizable sugar into glucose, if present in a heated solution.

“ 3rd.—Each part of glucose present is held in refining to convert another part of crystallizable sugar, and this with the allowance for ash reduces the available sugar from your sample to 24 per cent.

“ As a rule, we would decline sugar with so small a result.

“ My valuation is of course for refining purposes.

“ It is pronounced here less sweet to the taste than cane *goor* ; but it seems to me that, in small quantities, reaching the market early, it should bring top prices, viz., Rs. 3-8 to Rs. 4 per maund.

Sugar analysis.

Sample received—November 13th.

Marked Amber Sorgho *Goor*, 2oz.

Description—*Goor*.

Colour, &c.—light yellow—*Very acid*.

Composition.

| | | | |
|---------------------------------|-----|-----|--------|
| Cane sugar ... | ... | ... | 61.00 |
| Glucose ... | ... | ... | 23.85 |
| Ash ... | ... | ... | 3.15 |
| Inal. matter ... | ... | ... | 0.23 |
| Colouring matter extractive ... | ... | ... | 3.78 |
| Water ... | ... | ... | 7.99 |
| Total ... | ... | ... | 100.00 |

“ Available sugar 24.5 per cent.”

Messrs. THOMSON AND MYLNE.

“ The sample of *goor* you sent us is of the kind made for eating, and is not used for making sugar ; the present highest rates for eatable *goor* and *goor* for making sugar are 12½ and

15 seers per rupee respectively, and the value put upon your sample is 12½ to 12¾ seers per rupee.”

It may interest our readers to know that the Americans have succeeded in producing samples of the very finest sugar from sorghum ; 2½ lbs. of dry pure crystallised glucose, closely resembling loaf-sugar, has been obtained from a bushel of corn which can be sold at 2 to 2½ cents. In attempting to introduce this plant, the Cawnpore Experimental Farm has done good work, and it is much more pleasant and a good deal more profitable to read in Cawnpore Farm Reports of the sorghum plant and its “ potentialities ” than of the second-hand crudities of Lille about nitrogen.

ECONOMIC MUSEUMS.

THE Bengal Economic Museum is closed, and its collections are about to be removed to the Imperial Museum. For all practical purposes, it might almost as well never have existed, and we imagine that very few people in want of particular information about some industrial product of the country ever went to it to obtain what they wanted. This was not for want of specimens. Of some products, there was a bewildering superabundance of specimens. It seemed as if every specimen that came in had to be bottled and labelled, and every new bottle was supposed to add a new variety. This was not the fault of the gentlemen in charge—but it is useless now to enquire whose fault it was. Let us rather follow the old collections to their destination, and enquire whether there is a future life for the defunct Economic Museum.

It seems that there is at least a hopeful prospect before it. We gather from a resolution of the Government of India, which, though not yet published, has chanced to come under our notice, that larger and more liberal thoughts on the subject of the museum are at present struggling to the birth, and are really likely to shape themselves into a grand practical result. Though the resolution referred to is at present but slowly working its way through the hands of the provincial governments and administrations, we believe that the general idea of it has already met with a large amount of official approval. On the scope and probable utility of the idea, we may have more to say afterwards. But some general features of the proposed scheme and some considerations more or less closely connected with it, and with the forthcoming International Exhibition, may at the present time be profitably referred to. The new scheme may be briefly described as one for the consolidation and centralisation of all museums of whatever description and wherever located into a complete and uniform system, or into what, from the official point of view, might be called a single Imperial Department. The central administration of the museums would naturally devolve upon the Revenue and Agricultural Department. The living idea pervading the scheme is to make known and utilise to the utmost the industrial resources of India. The means employed will be to collect, to compare, to exhibit, to make everywhere easily accessible to every enquirer, the best procurable specimens of whatever nature man have been able to produce in this peninsula. The result, it is to be hoped, would be the revival of decayed or decaying industries, the stimulation and improvement of those now existing, and probably the creation of new ones. To come down from generalities, however, it is hoped to attain these great results through the agency of a system of museums, under trustees and local committees, but also under the central control of the Revenue and Agricultural Department. In each presidency or province, there would be a central museum, and in Calcutta the great Imperial Museum. In each division, or at any rate wherever a large city or town exists, there would be a divisional museum, and every important district throughout India would have its local museums. Thus in Bengal, there would be the central or Imperial Museum, and probably divisional museums at Patna, Dacca, and Cuttack, while such places as Monghyr, Krishnaghur, Berhampore, and many others would have local museums. Wherever any important industry was associated with a certain population, there would be a local museum, and the smaller museums would of course act naturally as tributaries or

feeders of the larger. The collections kept in the local museum would be confined to articles procurable in the district itself, together with samples of a better kind, if such were obtainable, from other parts, so that local art and industry might be taught in what it was defective, and stimulated to competition and improvement. It would also be important to keep all specimens in duplicate, so that the demands of Foreign and International Exhibitions might be met without any special labour on the part of district officials.

A very good example of a district museum may be cited in the neat and beautiful Monghyr museum, next door to the zilla school. This unique collection was made by Mr. Lockwood, a former magistrate and collector, now retired from the service, and is a standing memorial of the intelligent interest he took in his district, and the thoroughness with which he studied its characteristics and resources. By a glance at the coloured map, a visitor to this museum can see at once where and to what extent each product of this district is to be met with. If such museums could be established at all important centres, and attached in some way to our high schools or zilla schools, they would supply a great want in our system of education. They would afford the means of imparting scientific and industrial knowledge, and might be also so used as to stimulate among the boys a love of natural history, and give a useful turn to the boy's natural desire of making collections. Our system of education has been sadly deficient in any effort to shake off the apathy of Indian youths, and to train their powers of observation and their interest in natural objects. It does not appear in the Resolution whether this idea of associating the district museums with the high or zilla schools has been suggested to the authorities, and we therefore commend it to their consideration. While the museums might be made of the greatest use in the training of the young, the activities of the youth might be employed in enriching the collections. They must, of course, be under the superintendence of district committees, and the district officer would be *ex-officio* chairman of committee. Specimens of all the products of the district would be forwarded in duplicate or triplicate to the divisional museum, and by it to the central museum of the province, and thence to the Imperial Museum of Calcutta. Each specimen would bear a certain registered number permanently affixed, which would be the same in all museums where the article was exhibited. Thus the Imperial Museum would have specimens of all the important products of the empire, and each provincial, divisional, and district museum would have the specimens of its own province, division, or district. It is also in contemplation that duplicate specimens should be sent to the chief European museums, each bearing the registered number which it bears in the place of its nativity.

It will be seen that the idea is a large one, and yet, if systematically carried out under zealous supervision, it does not appear that there should be any insuperable difficulty in the way of its realisation. It would be a work of some time, but if once the main lines of the scheme were practically laid down, steady and gradual progress towards completion might be secured by intelligent superintendence.

THE TRADE OF ASSAM.

WE learn that the total river-borne trade of Assam, for the year 1881-82, reached a value of Rs. 1,95,61,593 for imports, and Rs. 3,62,86,691 for exports. The trade of the Brahmaputra Valley with Bengal and the trade of the Surma Valley contributed to these results in the following proportions:—

| | Imports. Rs. | Exports. Rs. |
|--------------------|-----------------|-----------------|
| Brahmaputra Valley | 97,43,704 | 2,26,21,130 |
| Surma Valley | 98,17,889 | 1,36,65,555 |

Compared with the results of the year 1880-81, the trade of the Brahmaputra Valley with Bengal shows an increase in value of Rs. 17,88,002 under imports, and a decrease of Rs. 3,57,540 under exports. The increase in imports occurs chiefly under piece-goods (European), gram and pulse, rice and liquors. A more extensive demand is gradually springing up for piece-goods of European manu-

facture, and the trade, it appears, is being pushed further and further into the interior by the Marwari merchants. The large import of twist and yarn proves that the native weaving industry still survives in many places. Most of the liquor imported is consumed on the tea gardens, and during the year under report there was an increase of little over half-a-lakh. The decrease under exports appears only under tea and oil-seeds. Compared with 1880-81 there has been a falling off in value of Rs. 8,91,300 in the exports of tea. We observe, however, that the local Administration is inclined to doubt the accuracy of these figures. The tea report for 1881 showed a crop of 23,725,026 lb, or taking the maund at 82 lb 2 oz., 2,88,889 maunds. In the previous year 1880, the report showed only 21,493,639 lb, or 2,61,718 maunds, while the export returns showed 3,03,609. It is believed that the crop for 1881-82 was greater than that of the previous year, not only from special tea returns, but also from figures furnished by tea-brokers, which give an out-turn of 24,390,732 lb in 1881, against one of 24,021,375 lb for 1880. As regards the other articles of export, we see that there is a considerable increase during the year under report under rubber, and that the jute export has nearly doubled, while the export of lac has more than doubled. A satisfactory increase also occurs in the exports of silk.

The trade of the Surma Valley shows an increase in value under imports and exports of Rs. 9,08,215 and Rs. 7,91,248 respectively. The increase occurs chiefly under cotton piece-goods, the value of which carried up-stream has risen by 9 per cent; tobacco which shows an advance of 56 per cent over the imports of 1880-81; salt, the increase in which exceeds 23 per cent; and oils, under which there is an increase of 113 per cent, and is ascribed to the more extended use of kerosine oil. The export trade shows an increase under tea of 16,050 maunds, or 9.5 per cent, and under paddy the exports amounted to 10½ lakhs of maunds against 1,63,260 maunds. There is also an increase of 5,47,690 maunds in the exports of lime during the year. The monopoly which formerly existed in this important business, has now been broken up by the local Administration, and the policy is stated to be at length bearing fruit in increased production and wider markets. It appears that limestone was never before so cheap as now at the marts on the Surma river, where it is delivered from the quarries on the Khasi hills. In June last limestone is said to have been sold at Rs. 135 per 1,000 maunds.

Some interesting information is given in the report regarding the coal-fields of Upper Assam, and we learn that those situated on the northern face of the Naga hills from the Dehing east of Makum, westwards to Dessai, are to become available as a store of force in the development and industrial progress of the province. In the Makum hills we see it stated that the coal-measures, in thickness and quality of coal, are among the first in the world, and are practically inexhaustible. It is also stated that the coal in the neighbourhood of the Dikhu river in Sibsaugor, west of the Dehing fields, may soon be brought under profitable working. The report goes on to say that "on the side of Sylhet and Cachar there are, it is true, coal deposits in the Khasi and Jaintia, and possibly in the North Cachar hills, while a fine field exists in the heart of the Garo hills on the Somoswari river, up which one of the projected lines of rail would be carried, but so much as is known of the Khasi hills coal, which is for the most part situated in places difficult of access, and occurs in 'pockets' or hollows, with seams which rapidly die out, each pocket covering but small area, does not make it probable that coal from this source could compete with the massive, easily-worked, and almost inexhaustible coal-measures of Makum, and as Raneegunge coal can under-sell that from Cherra at Sylhet itself, there seems no reason why Makum coal, if conveyed across the hills, should not under-sell at the same place coal from Raneegunge."

FOREST ADMINISTRATION IN HYDERABAD.

THE report of forest administration in the Hyderabad Assigned Districts for the year 1881-82 shows that good progress was made during the period in re-classifying the district forests. The forest area of the province stood

at 4,424 square miles on the 31st March 1882, or an increase of 168 square miles over the total area of the preceding year. The changes which occurred during the year under notice are exhibited as follows :—

| DESCRIPTION. | AREA IN SQUARE MILES. | | | |
|---------------------------|-----------------------|--------------------|-----------------------|---------------------|
| | On 1st April 1881. | Added during year. | Excluded during year. | On 31st March 1882. |
| State Reserves | 960 | 126 | | 1,086 |
| District Reserves | 420 | 8 | 126 | 302 |
| District Unreserves | 2,870 | 260 | 100 | 3,030 |
| Total | 4,250 | 394 | 226 | 4,424 |

The transfer of 126 square miles from the district reserves to the State reserves, and the addition of 260 square miles to the district unreserves, were the chief modifications during the year. We observe that the demarcation of the State reserves is stated to be almost complete now.

There were 369 prosecutions for breaches of forest rules during the year, of which 309 resulted in convictions. It is said that new rules have been drawn up for the province, and that the Forest Act of 1878 will no longer apply to the Berars when they have been once introduced. Compared with the preceding year, the results of fire protection during 1881-82 have not been so successful. The area attempted to be protected was 599,304 acres, while the area actually protected was 552,931, resulting therefore in a failure of 46,373 acres. We see it stated, however, that the injury caused by fires was not very great. In four cases, they were caused by lightning, while in nine, they were the work of incendiaries. The Conservator of Forests brings to notice, as one of the effects of fire conservancy, the enormous increase in insects—an evil which, it is said, is beginning to be felt more and more every year. Among the insects, he mentions a caterpillar, which, in the first break of the rains, especially if it is a long one, attacks the teak tree in swarms, leaving it almost bare of foliage, and thus checking its growth to a serious extent. Teak seedlings, too, it is remarked, suffer great injury from an insect which buries its eggs in the latest growth. On the production of the larvæ, large excrescences are raised, and the leading shoots ultimately killed.

The financial results of the year have not, it appears, been very favourable, and the State and district reserves both show a decrease in the revenue. The receipts of the year have amounted to Rs. 2,33,815, or a falling off of Rs. 32,741 compared with the revenue of the preceding year, while the expenditure, which has been Rs. 1,51,693, shows an increase of Rs. 22,724 over the charges of 1881-82. The decrease in revenue of the year is due to a falling off of Rs. 8,103 in the sale of timber of Rs. 4,280 in the sale of bamboos, and of Rs. 22,437 in the sale of grass and grazing fees.

COTTON IN BOMBAY.

MR. PRITCHARD'S report on cotton for the Bombay presidency, for the official year 1881-82, has earned the thanks of the Local Government for the interesting and valuable information which is supplied in it. The cultivation of cotton is extending very satisfactorily in that presidency, as will be seen from the following figures. The area sown with cotton during the year is shown as 4,811,146 acres as against 4,193,154 acres in 1880-81, while the estimated outturn has risen from 1,929,772 cwts. in 1880-81 to 2,578,555 cwts. in 1881-12. Although these figures may be capable of improvement, the Local Government thinks that they may be safely taken to prove that cotton cultivation is making great progress. The increase in the area sown is most apparent in the central division and particularly in Khandesh, where more than one-third of the whole cotton produce of the presidency (exclusive of native states) was grown. Here we observe that a much larger area was devoted to cotton than in the previous year, because the prices of food-grains had fallen low. Dharwar, Khaladgi, Hyderabad, and Kattiawar all show good increases in the area sown during the year. The average yield per acre of land sown with cotton, compared with the results

of the previous year are given as follows, for the several divisions of the presidency :—

| | 1880-81. | 1881-82. |
|----------------------------------|----------|----------|
| | lbs. | lbs. |
| Northern Division | 61 | 72 |
| Central " | 20 | 53 |
| Southern " | 29 | 38 |
| Sind | 205 | 155 |
| Native States, Northern Group .. | 70 | 72 |
| " Southern Group | 53 | 30 |
| Total | 52 | 60 |

The total estimated value of the cotton crop raised in the Bombay presidency during the year under review is shown as Rs. 5,49,18,356, against 4 crores, the value of the preceding year's crop. The average retail prices of cotton ruling in the different districts during the year varied from Rs. 11-4 per maund (Indian) in Surat to Rs. 23 per maund in Broach, while the wholesale prices ranged from Rs. 9 per maund in Surat to Rs. 19-3-7 per maund in Poona. We observe it stated that 90 per cent of the total production of cotton was indigenous cotton and the remaining 10 per cent exotic. The latter variety is chiefly grown in the Khandesh and Dharwar districts, where there has been an increase over the preceding year both in the acreage sown with exotic cotton and in the aggregate outturn. The production of the year of this variety amounted to 282,266 cwts., or an increase of 164,298 cwts. over the outturn of the previous year. Although a good deal is being done to induce cultivators to give up the cultivation of the inferior indigenous variety of cotton in Khandesh and to take to the exotic variety, we see it remarked that as the Deshi variety—one of the inferior indigenous kinds—requires less rain than the exotic, people are induced in seasons of insufficient rain to favour the cultivation of the former in preference to that of the latter. The produce per acre of exotic cotton in the districts in which it is grown varied from 19 lb to 104 lb.

The cotton trade is reported to have been unusually brisk during the year. The total quantity of cotton imported into Bombay by sea and rail was 6,325,618 cwts. as against 4,279,535 cwts. in the previous year; while the exports from Bombay and the ports of Kurrachee and Karwar were 5,462,854 cwts., or an increase of 2,319,929 cwts. over the exports of 1880-81. Of the imports by sea into Bombay, which amounted to 1,962,204 cwts., we find that 43,764 cwts. came from Persia, 30,880 cwts. from Madras, 63,619 cwts. from Sind, 710,876 cwts. from British ports in Konkan and Guzerat, 152,234 cwts. from Cutch, 929,937 cwts. from Kattiawar, and 23,085 from foreign Konkan; while quantities, varying from 3 to 1,600 cwts., were also imported from certain native states, and from Bengal, Burmah, Goa, Diu, Muscat, Suez, Hong-Kong, Genoa, and Venice. Of the imports by rail—1,364,411 cwts., the Bombay, Baroda and Central India Railway brought into Bombay 1,266,920 cwts., and the Great Indian Peninsula Railway 3,096,524 cwts.

The export trade with the United Kingdom, Belgium, Greece, Austria, Russia, Italy, and China shows a great improvement over that of the previous year, while the exports to Germany, France, Holland, and Spain have fallen off somewhat. The countries which took the largest quantities during the year were—

| | 1880-81. | 1881-82. |
|----------------------|-----------|-----------|
| | Cwts. | Cwts. |
| United Kingdom | 1,032,098 | 2,902,166 |
| Belgium | 62,975 | 224,085 |
| Greece | 1,760 | 7,210 |
| Austria | 507,694 | 600,638 |
| Russia | 13,760 | 16,115 |
| Italy | 558,743 | 780,868 |
| China | 130,932 | 186,983 |

In regard to the trade with the United Kingdom during the year, it is remarked that the exports were the largest recorded for many years past, being very little less than the aggregate of the exports to the same country in the past three years. The increase, it is said, is partly due to the disturbed state of Egypt, which caused a heavy falling off in the exports from that country to the United Kingdom, and partly to the abundance of the Indian crop and the consequent fall in the market rates. The report

says "that the aggregate value of Indian cotton imported into the United Kingdom during 1882 was 86 per cent higher than the value of the average annual imports of similar cotton during the last five years; and represents 24 per cent of the total value of all cotton imports during the same period." The report goes on to say that "the prices for cotton ruling in the Liverpool market in 1881-82 were slightly better for the Hinghaughat, Dharwar, and Kumta varieties than in the preceding year, and compared favourably with the prices ruling for the same varieties in the Bombay market, which were somewhat lower than the average of the preceding year. Broach and Dholera cotton commanded the same average prices in Liverpool in 1881-82 as in the previous year, though these varieties were quoted at a somewhat lower figure in the Bombay market than in the previous year. Neither market was quite as firm for Amroati and Sind cotton as in the preceding year, the quotations for 1881-82 being below those for 1880-81."

There were 49 cotton mills working and in course of construction in the Bombay presidency at the end of June 1882, against 42 in the previous year. The mills, it is said, find employment for upwards of 37,000 souls, and machine spinning and weaving is one of the most thriving industries in the presidency. The number of cotton presses working in 1881-82 was 247, of which 90 were worked by steam power and 157 by manual labour. The number of bales pressed by the cotton presses in work in the town and island of Bombay amounted to 500,274, against 359,724 in 1880-81.

In regard to certain remarks which Mr. Pritchard makes, to the effect that adulteration of cotton is increasing since the repeal of the Cotton Frauds Act, the Bombay Government observes that "the repeal of the special Act for the prevention of cotton frauds was forced upon Government, as its enactment had been demanded by what was understood to be a general consensus of mercantile opinion, and Government cannot be expected to re-consider the question except on the strongest proof that the repeal of the Act has led to frauds so extensive that, in the public interest, renewed interference is necessary and is demanded by the general opinion of the mercantile body interested in the question; but a question of such vital importance to the trade of the presidency will not be considered closed, while there is room for any doubt whether the mercantile community was right in pressing for a repeal of the Act."

COTTON IN HYDERABAD.

THE cotton report of the Hyderabad assigned districts for the year 1881-82 shows that the area under cotton cultivation has risen from 1,767,851 acres in 1873-74 to 2,189,688 acres in the year under report. Compared with the results of 1880-81, the area in 1881-82 shows an increase of 433,742 acres. The great falling off in the area of the preceding year is, however, explained by the fact that the fields had to be re-sown two or three times, and even then they are stated to have sometimes failed, owing to the light rainfall at the beginning of the monsoon. The area of 1881-82 is distributed in the following proportion between each district:—

| | Acres. |
|-------------------|---------|
| Amraoti | 489,917 |
| Akola | 590,107 |
| Ellichpore | 258,520 |
| Booldana | 314,614 |
| Woon | 297,654 |
| Basim | 247,876 |

The proportion which the area under cotton bore to the total area under crop in each district is given as follows:—

| | |
|---------------------|-------------------|
| Amraoti ... 34·2 | Booldana ... 26·3 |
| Akola ... 44·4 | Woon ... 28·9 |
| Ellichpore ... 41·7 | Basim ... 23·0 |

Of the different varieties of cotton cultivated in the provinces, we find the ordinary *bani* occupying an area of 1,483,803 acres, the ordinary *jari* an area of 673,408 acres, the Khandeish cotton an area of 17,743, American cotton an area of 13,592 acres, and Hinghaughat cotton an area of 142 acres. The quality of the crop is reported to have been above the average, while the quantity was also ordinarily large. The average out-turn per acre for the six

cotton districts varied from 9½ seers in Basim to 39 seers in Woon. The total production of the year in uncleaned cotton is shown as 5,637,652 maunds, and the total outturn of cleaned cotton as 1,409,413 maunds. The local administration is, however, inclined to think that the production of cotton has been under-estimated. The total exports of the year by road and rail amounted to 1,572,052 maunds, and the total imports were 56,844 maunds. Of the total exports, Bombay took 315,940 bales of 3½ cwt., the North-Western Provinces 4,083 bales, and the Central Provinces 3,214 bales. The stations from which cotton was chiefly exported during the year were Amraoti, Multasapora, Akola, Shegaon, Khangaon, and Malkapora, the exports from these places amounting to 323,237 bales. The average ruling price of cotton varied from Rs. 15-5-0 to Rs. 18-8-0 per maund of 40 seers. The average rate prevailing during the year was about Rs. 17 per maund. It is remarked that it has not been possible to ascertain to what extent the villagers sell their cotton at the large markets, and to what extent they dispose of it to village buyers. It is believed, however, that the latter course is being more and more adopted every year.

The cost of cultivation, including rent, is estimated to be about Rs. 4-8-8 per acre, and the total value of cotton, including seed, to be Rs. 19-8-8, thus leaving a net profit of Rs. 15 per acre to the cultivator.

The imports of rubber only amounted to 959 maunds against 1,228 maunds brought down in 1880-81, and was valued at about Rs. 40 per maund. The hillmen are said to have nearly exhausted the supply by reckless tapping of trees. The trade with Manipore has fallen off considerably during the year under notice. The imports reached a value of Rs. 28,812, against Rs. 26,110 in 1880-81, while the value of the exports was only Rs. 33,951, against Rs. 1,26,038 in 1880-81. The decrease in the exports occurs almost entirely under cotton piece-goods (European) and cotton twist. The falling off in the demand is, it is believed, due to the fact that the large quantities of cotton goods and twist which were exported during 1880-81, must have also have been deemed sufficient for the requirements of 1881-82. It appears that the Manipooris, in order to save the cost of conveyance, which, owing to want of proper roads, is not small, take large quantities of articles at a time, and keep them in store for future use.

We observe that sixteen steam cotton presses were at work during the year, the number of bales turned out by each press being as follows:—

| | Bales. |

EDITORIAL NOTES.

THE Government of Madras has recently published a report of the visit of a party of ryots from Villupuram in South Arcot to the Government Agricultural Farm at Saidapet, which is very interesting, as illustrating the impression derived by the ryots from a personal observation of the working of the different kinds of ploughs, the various kinds of machinery, and after a careful inspection of the several experimental crops grown on the farm. Of the several ploughs which were tried before the visitors, they fancied three kinds, viz., the Ransom wooden stilted (one stilt), the improved country plough wooden stilted, and the Swedish plough (one stilt), and consider that the

last named works much better than the one of the same class that has double stiles. They have asked to be supplied with a specimen of each of the three ploughs referred to, together with a light drag harrow which was shown them, and which they are anxious to try. It is their intention to have a number of ploughs manufactured of the three specimens which have most pleased them; these will be made of country wood and iron, and turned out by their own village artisans. Of other agricultural implements, the ryots have expressed a wish to be supplied with two "breaking machines of ground-nut cakes."

Amongst the live-stock of the farm, a good bred ram, with the longest tail and big head, has been asked for by some of the party for purposes of breeding. Others have taken a fancy to a Kerry cow, and a bull brought forth by it, and it is perhaps likely that they may be sold to the ryots wishing to have them. As regards the experimental crops on the farm, we observe that a quantity of guinea grass, which was shown to the ryots as being fit fodder for cows, has been asked for with the view of planting them in reserved tracts of their holdings. A number of trees of the manilla hemp is also to be supplied for purposes of experimental cultivation. A crop of the New Orleans cotton, which was inspected by the party, has also taken the fancy of some of the men, and they have asked for seed in view to try its cultivation in Villupuram. A water lift, drawn by a single bullock, was fancied by two of the party, and they wish to have it manufactured of country wood by the aid of a skilled person to be deputed from the farm to Villupuram. The ryots, it is said, were also anxious to try the cultivation of Chinese sugar-cane and the amber sugar-cane. Some of them are of opinion that these two varieties, more or less resembling a *cholum* crop, will be best suited for cultivation in South Arcot soils, although others are doubtful on the point. The following were selected by the ryots from the botanical portion of the farm, as the most fitting objects for trial in Villupuram:—

TREES.

1. Eucalyptus bicolor.
2. Do. rostrata.
3. Do. sidrophlio.
4. Do. gonicalyt.
5. Pandanus odoratissimus.
6. Acacia prosanthra.
7. Mahogani.
8. Anogeissus acuminatus.

FLOWER KINDS.

1. Bougainvillea spectabilis.
2. Porana volubilis.

The Madras Government, in its remarks on the report of the visit, trust that this will induce others to come and see what the farm is doing, and to adopt its improved methods and accumulated experience, to their own and the country's very great advantage.

PROFESSOR COMSTOCK says the most satisfactory remedy for scale insects is concentrated lye, one pound to one gallon of water. It does not injure the fruit buds, and most effectually destroys the scale insect. Whale-oil soap and sulphur mixture is a good remedy in summer, in the proportion of one pound of soap to one gallon of water. The application of the remedy to small trees is an easy matter. For large trees a bamboo rod ten feet long, with spray-tip nozzle, has proved of great value. This rod may be attached to a force-pump. In fighting scale insects on shrubs and trees all efforts to destroy them by poisonous fumes and by powdered substances have proved unsuccessful. Pyrethrum has done more harm than good by killing useful parasites in large numbers, with no appreciable effect on the scales.

At the last meeting of the North American Bee Association, a committee was appointed to gather statistics. It is believed that full statistics as to the number of colonies of bees and the product from them will surprise everybody, and lead apiculture to be better appreciated as one of the important industries of the country.

From a paper upon "Breeds of Sheep and their Origin," read before the State Wool Growers' Association, by the Hon. Robert Mitchell, of Princeton, Ind., we gather that the original importation of merino sheep into the United States from Spain, included all the most prominent Cabanas of that country. But, as a general thing, the different families, even when preserved pure from foreign admixtures, were crossed promiscuously with each other. The Saxon, French and Silesian merinos were of later importation. Of the original Spanish stock but two are now represented by distinct families, namely, the infantado and the paular. These sheep, originally imported by Colonel David Humphreys, of Connecticut, have been preserved pure to the present day. They are a fourth, if not a third, heavier than their Spanish ancestors, and are the largest family of American merinos. It may not be out of place here to give a short history of how the first Spanish sheep were brought into the United States. The following is from the pen of Mr. William Jarvis:—

"In 1801, General Humphrey, being then minister plenipotentiary at the court of Spain, purchased 200 of these sheep in that country and shipped them for their place of destination. They arrived in the spring of 1802. It seems to have been a custom at the Spanish court, when a foreign minister was recalled, on taking leave, a present was made to him of five or ten bars of gold, each bar weighing a pound, or thereabouts. But, as the law of his own country forbids any minister taking presents from a foreign government, he declined this overture, and suggested to the Spanish minister that royal license be granted to take out of the kingdom 200 merino sheep, which would be a great gratification to him. This the Spanish minister stated could not be done, but intimated to the general that if he wished to take them out, no obstruction should be thrown in his way. The sheep were accordingly procured and forwarded."

ALTHOUGH great efforts have been made, says the *Farmers' Review*, during the past few years to increase the supply of cattle for market, and large amounts of capital have been invested in ranches, and stock cattle in the South-west, North-west, and far West, extending from Texas to Oregon, from which we are already receiving liberal returns in the shape of fat beef cattle, many of which compare well with the grain-fed stock of the older States, the demand has responded so closely to the increased supply, that there is often cause for complaint in regard to the scarcity of desirable stock with which to supply the demand. This scarcity of fat cattle is largely attributable to the rapid growth of the population of the country, in connection with the wonderful development of our foreign export trade in dressed beef and live cattle during the past few years. The business of canning fresh beef, which was scarcely known a decade since, is now a prominent factor in the cattle market, the takings by Chicago canners being estimated 4,000 to 5,000 head per week. The goods thus put up find their way to all the leading countries of Europe. They also constitute the chief article of meat used in the far Western and South-western mining camps, where it would be impracticable to handle fresh beef, even if it could be had, and in many localities it would be impossible to obtain it. The mining camps of old Mexico are also largely supplied with canned meats from Chicago and other cities. Canned beef is rapidly superseding the salt junk which for ages has been a leading factor in vessel supplies. It will therefore be seen that the steadily increasing outlets for fresh beef promise to keep pace with the production, hence there is little cause to fear that the efforts now being made to increase the supply of beef will, in the near future, over-stock the market to such an extent as to cause prices to drop to figures that will not only, as some predict, render the business of raising beef cattle unprofitable but involve those who engage in it, in financial ruin.

The island of Jersey, having a surface of seven miles each way, keeps 12,000 cows. The breeding of cows has made the island very fertile; as the animals are kept in stables all the year round, every particle of the manure is saved. In winter they

are largely fed on parsnips, which has probably helped to develop the butter superiority of this breed of cattle.

MR. J. T. ALLEN, of Omaha, has presented some large figures as to the cattle-raising capacity of Nebraska. It appears that during the past year 90,000 steers had been shipped East from there, and that there were now 300,000 head of cattle grazing in the western part of the State. He estimates that the lands west of the Missouri river would support 5,000,000 cattle and 10,000,000 sheep, and supply for shipment yearly 650,000 cattle, 1,500,000 sheep, and 50,000,000 pounds of wool. He stated that the expense of raising a 1,200-pound steer was \$6, and that the entire cost of the animal delivered in Chicago was \$11.

MR. HUGH CLEMENTS, writing on the cost of cultivation in England, says:—From the average cost of the various items making up the total cost of the production of the several crops raised, which I have calculated, it will be found that the expense incurred in the cultivation of the land is excessive in many parts of the country, and does not produce an extra return at all proportionate with the increased expenditure. In England the average cost per acre for gross rent for the growth of wheat is about £1 18s. 7d.; for seed, 14s. 7d.; for manure, £1 14s. 8d.; for cultivation by hand or steam power, including harvesting, £3 3s.; for labour, including thrashing and marketing, 17s. 8d.; and for sundries, including tradesmen's bills, &c., 4s. 5d.—making a total of nearly £7 13s.

In Lincolnshire, farmers can apply 30s. worth of manure per acre, and raise wheat at a cost of £7 2s. 10d., including charge for interest at 7½ per cent.: in north-west Suffolk the same can be done for £6 12s. 3d.; at Darlington, Yorks, for £6 10s. 7d.; and the fallow crop in Huntingdon costs £7 1s. 11d., while that at Darlington amounts to £10 1s. 2d.: but this latter estimate might economically be reduced by 20s. on ploughing and harrowing, 15s. on manure, and 5s. on gross rent, bringing the sum down to £8 1s. 2d. Taking £7 as the fair charge for the cultivation of wheat in rotation, I find that the small proportionate amount of fallow wheat should only raise that average to £7 12s. 6d., which is virtually equal to the sum of £7 12s. 10d., the average obtained from the actual cost incurred in every part of the country. At Woodbridge, in Suffolk, the cost is £10 7s. on a mixed soil, and only £7 5s. on heavy land, there being £3 more manure applied in the former case, as well as 5s. more for seed, and nearly double for labour, including that of thrashing and marketing. At Reigate, in Surrey, £14 6s. 6d. is spent per acre in the production of fallow wheat on clay land, being £6 13s. 8d. above the general average, £4 being readily accounted for by excesses of at least £2 7s. in manure, 17s. in cultivation, including harvesting, and 16s. in gross rent, £10 6s. 6d. being ample for the production of wheat on the soil referred to.

The average cost of the production of barley per acre is about £6, made up of £1 16s. 7d. for rent, including rates and taxes, 12s. 11d. for seed, 15s. 9d. for manure, £1 14s. 7d. for cultivation, 16s. 3d. for labour, and 4s. for sundries. But I consider this average about £1 too high, there being no additional return at all equivalent to the increased expense. In Durham a good deal of barley is raised at from £3 12s. to £4 12s. per acre; in York, from £4 to £5; in Rutland, from £4 10s. to £5; in Lincoln, from £4 to £6; in Hants and Dorset, from £3 10s. to £1 10s.; but in many parts of Yorks, Lincoln, the other eastern and southern counties of England, the cost mounts up to £6, £7, and £8, and in some cases to nearly £9, the average charge in Kent being about £8 3s. 4d. per acre. The average spent in manure per acre is about 15s. 9d., but we have in some cases in Durham, 30s. and 50s.; in Yorks from 20s. to 60s.; in Lincoln, from 20s. up to even 80s.; in Wilts, 15s. to 20s.; in Kent, from 25s. to 40s.; in Hants, 20s.; in Devon, 25s. to 40s.; and in Cornwall, from 10s. to 50s. There seems to be great extravagance in manuring for barley, and as far as this crop is concerned, the results, as shown in the yield, are not so apparent as might be expected, for it often happens that the produce is as much, if not more, without the misapplication of manure. The manure may be and doubtless is often, beneficial to succeeding crops, and in keeping up the efficiency of the soil: but from an ex-

amination of the table given, it would appear that a large expenditure on manuring for barley is not justified by the results. There is little or no application of manure to barley taken after turnips, but there usually is when following a wheat crop. On a farm in Lincolnshire £1 10s. is spent in manuring after turnips, and £4 after wheat. Again, the amount spent in cultivation and labour might in many instances be reduced from 10s. to 20s., and even £2 per acre without seriously impairing the result.

The average cost for the production of an acre of oats is made up of £1 14s. 2d. for rent, rates, and taxes, 12s. 9d. for seed, 18s. 6d. for manure, 31s. 2d. for cultivation by hand or steam power, including harvesting, 14s. 9d. for labour, including thrashing and marketing, and 4s. 3d. for sundries—giving a total of £5 13s. 8d. With regard to the table for oats, much the same may be said as to the extra expenditure incurred in raising the crop as in the case of barley.

GRAIN EXPORT FROM NEW YORK.—The grain export from New York during the year 1882, the returns of which have been published, present some remarkable features. The steady decline of shipment by sailing vessels in the last few years is most noticeable. In 1880 the exports by sail were 63,376,000 bushels, by steam 49,996,000 bushels. In 1881 the export by sail were 19,007,000 bushels, by steam 53,552,000 bushels. In 1881 the American wheat and corn crops were both short, and as a consequence, the exports of 1882 were thereby materially affected. The sale shipments for that year were 6,284,289 bushels, while those by steam were 39,978,449 bushels. After making due allowance for the shortage of 1881 in its effects on the exports of 1882, the conclusion is evident that steam will expel the sailing vessels from the grain trade. Another important fact to be noted is, that not a single bushel of grain was shipped to Europe from New York during the year 1882 in a vessel under the American flag. Out of a total of 46,162,738 bushels, 26,694,846 were shipped in English vessels in 1882.

THE exports of wheat, and wheat in flour, from all American ports to foreign countries, from Sept. 1, 1882, to March 31, 1883, inclusive, being the first seven months of the export year of 1882-83 (crop year), aggregated 92,740,000 bushels, an average of 13,248,571 bushels per month. The same ratio for the remaining five months ending Aug. 31 would give an average for the year of 158,982,852, bushels. It is more than likely, however, that the exports will average much higher during the last five months of the year, as such is usually the case, especially in years when, as is now the case, the estimates place the growing crops of Europe as likely to fall below the usual average, as millers and dealers there take the timely precaution to secure good supplies in advance.

PROFESSOR W. A. HENRY, of the University of Wisconsin, has made the following report on a sample of sorghum sugar submitted to him:—

The sample was manufactured from amber-cane grown on the experimental farm in 1882. The data of the largest plat of cane made into sugar this year, is as follows:—

| | | | |
|---------------------------------|-----|-----|----------------|
| Area of plat | ... | ... | 3 3-5 acres. |
| Weight of stripped cane | ... | ... | 76,262 pounds. |
| Per cent of cane sugar in juice | ... | ... | 9.89 |
| Per cent of glucose in juice | ... | ... | 3.95 |
| Amount of sugar separated: | | | |
| First crystallization | ... | ... | 2116½ pounds. |
| Second crystallization | ... | ... | 830 " |
| Total amount of sugar | ... | ... | 2,946½ pounds. |

Syrup drained from the sugar, 315 gallons.

Seed obtained, 76 bushels of 51 pounds each.

The cost of manufacturing the unrefined sugar was, for all expenses, including the cost of the cane, but excepting the pay of the chemist in charge, 4½ cents per pound. The value of the cane seed is not taken into account in the above estimate.

As the means of refining were very imperfect, the samples sent out vary greatly in color; some are nearly equal to light "Yellow C" in color, and appearance, while most are brown in

From the Director of Agriculture and Commerce, North-Western Provinces and Oudh, to the Secretary to the Government of the North Western Provinces and Oudh,—No. 403A, dated Allahabad, 17th March 1883

I have the honor to acknowledge receipt of your letter No. 312, dated 5th February 1883 (Revenue Department), calling for a special report on the sorghum sugar experiments of this department, and in reply to report as follows—

The field selected was manured with farm-yard manure and cultivated in the ordinary manner. It was divided into three sections, in which were respectively sown—

1st.—Early Minnesota amber cane received from the Government of India, a variety which bears the palm in America.

2nd.—Amber cane or red sorghum, from seed of last year's farm crop.

3rd.—Black sorghum.

In every way these crops were treated like an ordinary crop of *gundri*. The field, however, proved to be too low; and with water standing on it for some time in July, the crop proved a poor one, and not nearly so good as another crop of sorghum grown for fodder, only on land higher and unmanured. The low-lying crop also was much damaged by the "makal" grub which does so much injury to maize.

The experiments were directed solely to procuring the best possible sample of crystallised sugar in the compost form (goor). So far as could be understood from the reports received from other parts of India, no saleable goor had yet been made, and even in America the manufacture of anything but syrup would seem to date from about 1861.

Experiments were tried with various re-agents for defecting and clarifying the juice which is intensely acid, much more so than that of sugarcane.

Canes were cut at various stages of growth to ascertain the most profitable period.

Canes were ground with the leaves on to economise the labor for stripping.

The worm-eaten canes were excluded. So a great deal of the crop was used to gain experience, and scarcely as much was used in the manufacture of the best samples as would warrant the building up thereon of a commercial scheme. For this another season or two must be awaited.

The best results were arrived at by stripping the canes in the field, carrying them straight to the mill as cut, putting them through a *Bihm* mill at once, and boiling the juice in one pan, as soon as removed from the mill. The best time for cutting the canes is when the seed is in the dough stage. The head of seed is cut off with the top short, and left in the sun to ripen, the whole of the seed being saved. As economy is a great point, a portable mill that can be carried to the field is a desideratum. Fermentation converts crystallisable sugar into uncrystallisable. So does the acid in the juice at high temperatures. Fermentation is set up in the juice on exposure to the air, hence the necessity for getting the canes pressed and the juice neutralised as quickly as possible after cutting. To prevent fermentation also, the mill, boiling pan, and vessel for holding the juice as it comes from the mill were daily fumigated with a few sulphur matches.

A few drops of castor oil were sprinkled on the juice as it approached boiling point to aid in clarification, and at boiling point milk of lime was added carefully to a point close on neutrality.

The scum, as it rose, was carefully removed and the juice concentrated down to the proper consistency for goor. A small quantity of "rab" was made from which drained crystals were obtained as a sample; but attention was chiefly concentrated on making goor.

The above details show no difference from those of the process of manufacturing goor from sugarcane, as now practised by many manufacturers. It is only given in detail because, although goor may be made from sugarcane juice, without using lime, a skilful native sugar-boiler entirely failed in operating on sorghum juice without lime, and for the black sorghum the failure was maintained even with lime, until a small quantity of carbonate of soda, or *sajji*, had been added as well as the lime.

Taking an average, the result was as under.—

Output per acre.

| | Mds. |
|-----------------------|-------|
| 1. Weight of plant | 125 |
| 2. " of cleaned canes | 52.27 |
| 3. " of goor | 4.44 |
| 4. " of grain | 3.00 |

Cost per acre.

| Cultivation. | Mds. | Rs. | A. | P. |
|------------------------------------|------|-----|----|----|
| Manure | 100 | 3 | 0 | 0 |
| Ploughing | 2 | 1 | 8 | 0 |
| Crushing clods | .. | 0 | 4 | 0 |
| Sowing | .. | 0 | 12 | 0 |
| Seed | .. | 0 | 4 | 0 |
| Weeding (once) | .. | 2 | 0 | 0 |
| Cutting | .. | 2 | 8 | 0 |
| Rent (kharif) | .. | 4 | 0 | 0 |
| Boiling juice @ Rs. 1-12 per maund | .. | 7 | 14 | 0 |
| Total | ... | 22 | 2 | 0 |

Value of produce per acre.

| | Rs. | A. | P. |
|--|-----|----|----|
| Goor @ Rs. 4 per maund | 17 | 12 | 0 |
| Grain @ Rs. 0-12 per maund | 2 | 4 | 0 |
| Top and leaves of fodder @ 10 maunds per rupee | 8 | 8 | 0 |
| Vinegar | 1 | 0 | 0 |
| Total | 30 | 8 | 0 |

The analysis, by Messrs. Carew and Company, Limited, of a sample, was as under:—

| | |
|------------|--------|
| Cane sugar | 61.00 |
| Glucose | 23.25 |
| Moisture | 7.99 |
| Ash | 3.15 |
| Unknown | 4.01 |
| Total | 100.00 |

This analysis shows for refining purposes an objectionable amount of glucose and a larger amount than was present in a sample of sorghum

goor manufactured this year, also, at the Aska Sugar Works* in Madras. The sugar would clearly be more suitable for brewing purposes than for refining purposes so far as export is concerned. But a peculiarity of glucose sugar is, I believe, its similarity in taste to honey, a taste which was very marked in some samples of the sorghum goor, and which seems to be to the liking of the people.

Coming as it does out of season and forming a good eating goor, there is testimony from both Messrs. Carew and Company and from Messrs. Thomson and Mylne that it would fetch a top price in the market. It may possibly then become at least as popular for eating as sugarcane goor, and so free a large quantity of the latter for export, particularly, if, as may be hoped, further experience will lead to further improvement.

Sorghum requires no irrigation nor does it require much manuring. It can be grown on high light land which grows ordinary kharif crops, and has in America been cultivated year after year on the same soil without deterioration. The seed is all saved and is good food for man or cattle, while the tops, leaves, and bagasse are all eaten greedily by cattle. It is worth then the closer attention of Indian agriculturists; and a large supply for distribution should be indented for of the best early amber variety from America against the coming kharif season.

INDIAN TRADE WITH AUSTRALIA.

The following note, drawn up in the Revenue and Agricultural Department of the Government of India, has been published by the Government of India.—

The active co-operation of the Government in the promotion of Indo Australian trade, commenced at the Melbourne Exhibition of 1880, has now almost been brought to a close in the despatch of a final consignment to Sydney of Indian goods likely to meet Colonial requirements. These are consigned to the late Commissioner at the Melbourne Exhibition now resident at Sydney, the capital of New South Wales. The success of Indian exports in the market of Victoria, of which Melbourne is the capital, has been undoubted. Before 1880 the trade with Melbourne consisted mainly of raw jute, jute goods, castor oil, and rice. Exclusive of these and of tea, which then, however, formed a very small portion of the exports, the Indian consignments received at Melbourne were valued at Rs. 1,61,678. In 1882 their value was estimated at Rs. 5,43,355, or Rs. 3,81,677 in excess of the value of 1880. The goods exported through the Exhibition Agent, who after the Exhibition remained in Melbourne for the purpose of pushing the Indo Australian trade, were alone valued at Rs. 1,67,086 in 1882. A very large increase is taking place in the current year. The impetus given to Indian exports is to no small extent due to the success of tea, in the wake of which the minor articles of commerce have followed. Tea exports rose from less than a lakh of pounds in 1880 to over two millions in 1882. Other lines in which success has been prominent are soft goods, myrobolams, skins and hides, unrefined sugar, &c.

The demand for hides and skins in Australia, a country in which cattle and sheep abound, appears remarkable, but is due to the fact that Australian hides are too good for many purposes for which Indian hides are required. The latter are used, for instance, in making the upper parts of boots worn by the middle and lower classes, for which purpose also they are exported in large quantities to Europe. "Spices and Condiments" is not an entirely new line of trade, but has been extended by the Exhibition. Tanning materials are likely to find an increasing market in consequence of the exhaustion of forest products in Australia itself.

Certain of the cotton goods which the Melbourne Commissioner took considerable trouble to place before the Australian houses have found favour, and some classes of the Bombay mill hosiery

are likely to meet with considerable sale. A valuable market has also been found for a new class of jute goods, to meet which new machinery has been set up in more than one mill.

In consequence chiefly of the magnitude of the trade in jute bags, in which the Australians pack their wheat and wool for export to Europe, there has always been a very large excess of exports to Australia over imports from that colony. The increase in exports, therefore, however satisfactory, is not likely to assist in leading to the increase in direct shipping communication with Australia, unless some return trade is thoroughly established. The Australians do not send much to India now, except horses and metals. It is doubtful if there is anything else in the colony which they can afford to send to India in any quantity, except perhaps timber and ghee. The high price of labour precludes their competition in India to any manufactured article, or any production in which human labour is an important element. On the other hand, wool is at present not required; while frozen meat, butter and preserved fruits would only meet a small demand from the European population, and perhaps of a few wealthy sections of the native community. Timber might, however, be taken for public works, while the whole native population is a customer for ghee.

The quantity of the latter article consumed in British India, exclusive of Natives States is estimated by the provincial authorities at considerably over five million cwts. per annum, the value of which is about fourteen millions sterling. The price of ghee is gradually rising, owing to the continuous decrease of grazing land and the greater profits derived from the cultivation of produce. There is, therefore, some hope that the import of ghee from Australia, if once introduced, will meet a constantly rising market, and become more and more profitable.

The price now ranges between 5d. and 7d. a pound; but first-class ghee sometimes fetches in the Bombay market as much as 11d. a pound.

The attention of the Government of India is now confined to the import question. Unless a return trade from Australia can be found, the shipping rates will do much to handicap the extension of the export trade and curtail the Australian demand for Indian goods. One experiment has already been tried for the purpose of solving the ghee question. Two ghee-makers were shipped to Victoria; but the landowner to whom they were consigned found the adjacent butter market at Melbourne to be so lucrative that the ghee-makers' labour was quickly confined to the manufacture of butter. The experiment is now to be repeated on the condition that the labour of the ghee-makers shall not be diverted to other purposes. But it is in New South Wales, in that part of the country to which emigration is likely to be established, *viz.*, in the tropical regions on the north coast of Australia, that the industry is most likely to take root, and further experiments will be tried therefore on this occasion in the northern tracts of South Australia. In the meanwhile, it is anticipated that some samples of Australian ghee, with statistics of the cost of production, will be forthcoming at the Calcutta Exhibition.

SELECTIONS.

THE VITALITY OF SEEDS

AUTUMN is the natural season for the study of seeds. But most of us have our attention more particularly drawn to them in the spring; and in the months of March and April most amateur gardeners get their only personal knowledge of these mysteries of creation. Among the questions that are pretty sure to crop up in many an amateur's garden at this time of year are, whether the remnants of last spring's seed packets will do to sow this year, and how long may seeds be kept before losing their vitality. This opens up rather a wider field for investigation than would, perhaps, be supposed by those who have never given any attention to matters of vegetable physiology. As a rule, no doubt, most of the seeds which amateur gardeners are likely to have should be last autumn's. But seeds vary immensely in their vitality. Everybody has heard perhaps rather too much of the mummy wheat, which has been declared, seemingly on good authority, to have germinated after having lain in the palm of a mummy ever since the body was embalmed, perhaps 3,000 years ago. That idea, however, has now been very generally exploded. There can be no doubt that there was some want of care in the observations which seemed to establish it. This, however, is not the only observation of the same kind that has been adduced in proof of the indefinite vitality of some seeds. Dr. Lindley, for instance, the well-known botanist, says in one of his works, "I have at this moment three plants of raspberries before me, which have been raised in the garden of the Horticultural Society from seeds taken from the stomach of a man whose skeleton was found thirty feet below the surface of the earth, at the bottom of a barrow, which was opened near Dorchester. He had been buried with some coins of the Emperor Hadrian, and it is therefore probable that the seeds were sixteen or seventeen hundred years old." That statement also has, we believe, been rejected as the result of observation not sufficiently guarded, and it may, we suppose, be considered as generally improbable that seeds ever have the capability of germinating after the lapse of any such period. At all events, we have no well authenticated proofs of anything of the kind, though such alleged facts as that to which Dr. Lindley testifies have had the support of very credible witnesses. "The preservation of vitality," says an authority, "depends upon the stability of the chemical compounds of which they consist. This appears to be the hinge upon which everything turns." A further truth seems to be that the process of ripening is one which results in this stability. Oxygen is the great agent of change, whether of

germination or decay, and a ripe seed is one which has been fortified against the action of oxygen. In some seeds this process appears to be more complete than in others. Even when fully ripe, nuts and acorns have a greater affinity for oxygen than corn, or peas, or holly berries. Nut and acorns, therefore, lose their vitality more rapidly than any of the latter. In some seeds the ripening process appears to do very little towards fortifying against the all destroying oxygen. It is said that coffee berries, for instance, lose their living principle if not immediately planted, when they become fully ripe, and the same thing has been affirmed of magnolia seeds. On the other hand, all kinds of cereals appear to perfect their ripening process very completely under favourable conditions, and hence preserve their power of germination for a long time. Maize has been grown after lying by for twenty-five or thirty years; rye for forty years; and wheat—leaving out of consideration the gift of the mummies—has been known to yield a good crop after considerably longer than that. Dr. Lindley says that the seeds of the sensitive plant will keep for forty years, and kidney-beans for a hundred years. It has been recorded that, after the great fire of London, the ground cleared by the destruction of the buildings soon became covered with plants of a kind unknown, or very uncommon, in London previously; and prairie fires in America have been observed to have been followed by a similar phenomenon. Some have explained this—though there certainly appears to be no great probability in the theory—by supposing it due to the fact that seeds had been overbuilt or overgrown, and thus shut away from the vitalising action of the air, and that, when the ground was cleared above them, their suspended animation re-asserted itself, and they started into life. There would seem to be more probable ways of accounting for such a phenomenon, though it seems to be indisputable that good reason has occasionally been found to believe that seeds have been thrown up from a considerable depth in the soil, and have at once germinated, their vitality having apparently been suspended by burial. Amateur seed sowers should make a note of this. A very common mistake is that of burying seeds too deep in the soil. They get moisture, but they get too little sun and air, and fail to germinate. Usually no doubt they die, but it may be that some of the more enduring kinds may start into growth on being subsequently turned up to the surface, and it may be that the plentiful crop of weeds that will often overpread a newly dug plot of ground within a very short time, may be accounted for in this way. A very curious fact was vouched for many years ago, which has an additional interest now, that electricity seems to be invading every department of activity. It was found that a galvanic current had a decided effect in the germinating of seeds—that seeds at the negative pole of a battery germinated much more freely than those round the positive pole. But what is far more singular than this is that, according to very respectable authority, the radicals of seeds made to germinate at the positive poles grew upward instead of downward—the current made them grow bottom upwards. Professor Reufrey, who mentions this, refers to a number of experiments carried out with the definite object of ascertaining how long seed may be kept with a probability of their growing. Out of 368 species tested by De Camille, there were only seventeen that grew after a lapse of fifteen years. Out of 188 genera tried under the auspices of the British Association, it was found that the majority had lost their vitality altogether at the end of ten years. Thirty-four species retained a capability of germinating after ten years, twenty species after twenty years, and only two after forty years. As a general rule, there can be no doubt that Nature knows pretty well what she is about in shaking down her seeds as soon as they are ripe. They deteriorate by being kept. So far as the floriculturist is concerned, however, there would seem to be some exceptions. Balsam seed, for instance, is thought by many growers to produce more double blossoms by being kept for a time. As a rule, however, old seeds should not be relied upon, and, though it is to be feared that most of the seed packets have a certain proportion of old stock, we suppose that many dealers will satisfy any little qualms of conscience with the reflection that most amateurs are given to sowing their seeds too thickly.—*Globe*.

INDIAN AGRICULTURE.

IN what manner shall a rapidly increasing population derive sufficient sustenance from a deteriorating soil? To the solution of this problem Lieutenant Frederick Pogson, H. M.'s Bengal Army, has applied himself with much intelligence and assiduity. He is encountered, however, by two enemies—the apathy of the Government, and the prejudices of the people. Again and again, he has placed important information at the disposal of the Government, but only to find his warnings neglected, his good advice treated with indifference. The value of a rich opium crop, one would imagine, must be pretty well established by this time, and yet no attention has been paid to a pamphlet published in 1871 by Mr. Phillips, a landholder in the district of Fyzabad, in which were pointed out the great advantages he had derived from the use of a particular manure recommended by Mr. Pogson, who had officially communicated his formula to the local Government. Experience also has shown that the poppy is far more vigorous and hardy when grown on hills, and that Himalayan opium contains twice as much morphia as the best produce of Benares and Patna. Nevertheless, the cultivation of the plant is virtually confined to the plains, where the requisite iron, potash, and nitrogen are inadequately supplied by the soil, and to provide which was the object of Mr. Pogson's slighted receipt. In like manner, no

* *Manual of Agriculture for India* By Lieutenant F. Pogson, H. M.'s Bengal Army. Thacker, Spink & Co.

official steps have been taken to encourage the cultivation of the Chufas, or *Cyperus esculentus*, which, although imported by the Agri-Horticultural Society so far back as 1837, does not yet possess a Hindoo name. It is the well known ground nut, so popular in the United States and in Spain as food for human beings, as well as for sheep, cows, oxen, and pigs. It is described as extremely prolific, a single nut yielding from two to four hundred. In flavour it resembles a coconut, with a taste of almonds when the tubers are ripe and dry. A still more striking example of bureaucratic superciliousness is to be found in the stupid neglect of the immense deposits of fossil bones in the Sewalik range. The natives who, if Hindoos, can hardly be prevailed upon to touch bone-dust, do not object to handle the phosphatized bones dug out of these mountains, probably from not understanding their real character and origin. The one thing needful is the construction of cart roads, but hitherto Government has apparently had no time or thought to bestow on such vulgar details. The Hindoos are equally averse from using night-soil and liquid manure, and thus abstain from employing the means immediately at hand for the regeneration of their exhausted soil. Mr. Pogson is severely logical in rebuking the Hindoos for their laudation of the cow as a universal purifier, and yet refusing to make use of the animal for the purification of bone dust and other artificial manures held to be "common and nucleon." His advice, however, may be profitably followed by both native and European agriculturists, for it is eminently practical and devoid of empiricism. His little volume, indeed, embodies teachings of a large and varied experience, and deserves to be warmly supported by the Government.

The food question, indeed, is beginning to cause anxiety in almost every region of the globe. Even the Americans are watching with disquietude the rapid absorption of cultivable land by immigrants from Europe. The present system of agriculture in the United States, if such it can be called, where the soil is left to itself, is excessively wasteful and exhausting. So long as the virgin soil will go on yielding spontaneously, the danger of diminution in the supply of cereals cannot be imminent, but as soon as manure is wanted, the decline will become visible to all men. The American farmer is not generally a stock keeper, except on dairy farms, which, of course, produce little in the way of corn. But without stock it will be necessary to have recourse to the artificial manures which need to be applied with thought and discrimination. There is a very general belief that the prevalence of pleuro pneumonia is partly and even largely due to the excessive or injudicious use of artificial manures, uneducated farmers taking no heed of their component parts, or of the nature of the soil or crop to which they are to be applied. The Indian agriculturist who is willing to be guided by Mr. Pogson's advice, incurs no risk of the kind. He is not invited to purchase this or that compound, but is told in simple language, to be understood of all men, what he is to do for each particular crop, whether poppy or tobacco, maize, wheat, or barley, or any other form and fashion of field produce. He cannot go wrong unless he chooses to follow his own judgment. In England the outlook is very disagreeable, alike for those who own, and for those who occupy land. Lamb for the present is tabooed, which deprives the farmer of his spring resources. Even mutton is growing scarce and dear. Old mutton such as our fathers loved has long been unobtainable. It is seldom more than one year old, and is consequently pale and flabby. It has deteriorated as much as the claret with which it was washed down. Charles the Second may congratulate himself that he lived at a time when sheep were grass-fed, and suffered to complete their fourth or fifth year. He would never have been a merry monarch, had he sat down to alternate courses of beef and pork, the one out from an animal dying of consumption, and the other from an unclean beast swarming with trichinae. The very grape refuses to make glad the heart of man. *Phylloxera* is a long and hard word for the million, but the disease appears to be as incurable as young love, and much more fatal. The vile concoctions of Spanish and Australian wines combined with slow poisons, that are now shipped from Bordeaux, mark not only the deterioration of the French vine, but also, what is far worse, the deterioration of the French character. Man must live, however, or think that he must, nor will he live on bread alone. With the diffusion of sound scientific knowledge, the earth will once more be compelled to yield her kindly fruits in due season, and in sufficient quantity for the maintenance of mankind. The period of trial and tribulation is generally brief, and is usually succeeded by long continuous happiness, especially in three-volume novels. Let us hope, therefore, that man will not be starved off the face of the earth, at least in our time; and in the meanwhile we may perchance postpone the evil hour by a careful study of Mr. Pogson's treatise.—*Mutras Mail*.

ECONOMICAL USE OF TURNIPS IN THE FEEDING OF CATTLE

MR. BRUCE, Colthistle, read a paper on this subject at the last meeting of the Strathbogie Farmers' Club. After a few introductory remarks, Mr. Bruce said:—If the same proportion of the acreage of the farm is to continue to be devoted to the growth of the turnip crop, I would suggest as an improvement on the present mode of its consumption that the whole of the crop be drawn for sheep, and the number of drills left to be regulated according to the quality of the soil and its need of the manure of sheep. A great drawback, and it is a serious one, to the consumption of turnips by sheep in this district, is the heavy rainfall and stormy nature of the weather generally. Owing to such adverse climatic conditions as generally prevail here in winter,

prices for drawn turnips must be considerably lower than in other districts where a milder climate is enjoyed, and where the stock arrives sooner at maturity. And as the turnips are not worth so much to the flockmaster in this locality as in many others more highly favoured, owing to the same reason—the heavy rainfall and frequent snowstorm—it is highly probable that in even an average season the succeeding crops do not derive so much benefit from the droppings of sheep as they do in the more favoured localities. As prices as a rule may be expected to remain low—in fact seldom so high as sufficient to cover the cost of production, farmers have not the same encouragement to consume a part of the turnip crop on the ground by sheep as the farmers have, who live in districts where a dry climate is enjoyed, and which is so necessary to the speedy fattening of the fleecy flocks. However, if it be assumed that the manure left on the ground by sheep be worth to the succeeding crops about 30s. per acre—which I believe it is—when the turnips are consumed on ground in suitable condition, a little encouragement appears, and it might be worth the attention of farmers to try the system on a more extended scale than has hitherto been done in this district, and carefully watch the results. For economical reasons the present system of consuming the turnips is ripe for change, and an alteration is due at an early date, but owing to a spirit of apathy, which unfortunately prevails in farming circles, and which is altogether hostile to agricultural progress, I fear the necessary reform which agricultural enterprises should achieve, will only be accomplished by stern necessity. Turnips could be much economized by pulping and mixing with chopped straw, but as this mode of preparation cannot be conveniently adopted on every farm for want of water power, and, as in too many cases a prejudice prevails against the method, it has not had such an extensive trial as it deserves; but, as the prejudice is not born of personal interest, it would doubtless be removed by a clearer knowledge of the system and its attendant results. By pulping turnips and mixing with cut straw a considerable saving can be effected; in short, the supply of roots can be reduced to one-half the ordinary quantity (or from 150 lbs. to 75 lbs.), along with cake or meals to a feeding bullock per day, with a similar reduction to young and growing animals. Such a saving is a great consideration, and pulping is surely a mode of preparing food worth giving an impartial and exhaustive trial. Some people have abandoned the system of pulping roots in despair, on account of their stock not making satisfactory progress upon the prepared food; but upon inquiring into the whole system of feeding pursued in such cases, it appears that the animals were not supplied with water, and as water is requisite when the allowance of turnips is brought to such a limit, it would be a matter of surprise if the results in such cases were entirely satisfactory, seeing that nearly two thirds of the weight of the animal's body is composed of water. When roots are dirty, as they frequently are, when lifted in the winter months, it is necessary to wash them before pulping, not only to save the machine from unnecessary wear and tear and to prevent its destruction by small stones, but to present the food to the stock in a clean and palatable form. During the last few years the labour and expenditure of the husbandman have not been rewarded by full crops of turnips, and extensive resort has necessarily been had to artificial food, and it is probably during such seasons, when farmers are compelled to use artificial food, that its advantages become most apparent. As we must drift with the stream as circumstances direct, probably the best thing would be to somewhat alter our stereotyped rotation, and put a smaller breadth under what in this district we may call the 'sorry crop,' and rely to a greater extent on extraneous assistance in the feeding of stock. I advocate the more extended use of artificial feeding stuffs for three reasons. First—Because, if you pay for them you are sure to get them, whereas you may be at the trouble and expense in endeavouring to produce a crop of roots, and have a partial, amounting at times to almost a total, failure of the crop. My second reason is that I consider by a moderate use of concentrated feeding stuffs, and a limited allowance of roots, flesh and fat can be laid on the bones of our animals in less time and at less cost than by the common system of allowing them all the turnips they can consume. My third reason for advising the use of such substances is, because I believe the fertility of our fields can be considerably increased by the extra quality of the farmyard manure, in which a judicious mixture of the richer varieties of food has entered into the dietary of our stock. And I also believe that this extra fertility can be purchased at a less cost indirectly by the use of such food amongst the stock than by directly applying to the crops the expensive ammoniacal and phosphatic manures. Of course, it has to be borne in mind that in order to obtain the full benefit from the consumption of artificial food no waste should be permitted in the courtyard, and in order effectually to prevent waste, the manure heap necessarily requires to be covered, and the wash of the byres, without being contaminated with rain water, should be carefully conducted to the heap, and there preserved so far as can be absorbed by the manure. In the most economical feeding of stock, a knowledge is required of the exact relationship that exists between an animal and its food, and of the analysis of the various kinds of food. An acquaintance with physiology, together with the researches of chemistry, have given the necessary information, and by these lights which illuminate the otherwise dark paths of agricultural knowledge, I shall briefly consider the constituents of food, and refer to their relationship in the animal economy. The various constituents of food are divided into two distinct classes, the nitrogenous and the non-nitrogenous. The nitrogenous portions of food are albumen, caseine, and fibrine, and are called flesh formers because they form the blood and tissue of the body. The flesh-formers are present to a limited extent in the straw of cereals, but mostly abound in the seeds of beans, peas, lentils, oats, and wheat, while the seeds of cotton and flax are particularly rich in them. The non-nitrogenous portions of food are of two principal kinds—the oils and the carbohydrates, or starch, sugar, pectin, and gum. In the animal economy these

maintain the heat, promote respiration, and form fat. In Indian corn, in the straw of cereals, and in the dry matter of potatoes, starch is present in large quantities. Sugar and pectin are common constituents of mangolds, carrots, turnips, and other roots. In the animal system, oil serves two purposes, viz., for the maintenance of heat and for the storage of fat. For the purposes of respiration, oil has two and-a-half times as much value as the carbo-hydrates, because it contains that excess of carbon; and that portion of it which is digested goes for the storing up of fat in the system. Some of the leading physiologists have recently changed their views, and they now regard the carbo-hydrates as being useful in the animal economy only for the purposes of respiration and for the maintenance of heat. Formerly such substances were looked upon by all as being useful for the production of fat. However, it matters little; for were it not for the carbo-hydrates, the animal heat and force would necessarily require to be supplied by the albumenoids and oil present in the food. Science shows that the animal body is composed of the following four proximate elements:—1st, water; 2nd, albuminous tissues, represented in the food by nitrogenous matters or flesh-formers; 3rd, fatty tissues, being represented by hydro-carbons or fat-formers and heat-producers; 4th, saline, having its corresponding representative in salt. It therefore follows that, in order to maintain the animal system in health, it must be supplied with food containing all the constituents of its composition. Physiology has given well-defined principles, sufficient for the purpose of properly regulating the diet according to the intention of the feeder. Thus young and growing animals should be supplied with food best adapted for the building up the lean part of the body, or for giving them bone and muscle. For this purpose gluten or albuminous matters are absolutely necessary, and should occupy an important place in the composition of their food. The amount of flesh that can be derived from food depends upon the quantity of albuminous constituents present in the food. For the full development of muscle, animals should have plenty of exercise, and they should also have access to salt, which is necessary in the animal economy. Feeding animals, on the other hand, should be supplied with food most conducive to the production of flesh and fat, and for that purpose the oleaginous food, or substances rich in fat and oil, should be mixed, in suitable proportions, with the albumenoids or flesh-formers—i.e., albumen, caseine, and fibrine—and the carbo-hydrates for heat givers—i.e., starch, sugar, pectin, and gum. Having considered the various constituents of food, and their respective uses in the animal economy, I shall now briefly refer to the analysis of the common varieties of food produced on the farm. My analysis we find that turnips contain fully 90 per cent. of water; it consequently follows that there is scarcely 1lb. of dry feeding matter in every 10lbs. of them, and in that small quantity of dry matter there is no oil for the rapid accumulation of fat, and only 1½lb. of albumenoids or flesh forming compounds; they contain, however, about 5½ lbs. of the carbo hydrates or non-nitrogenous constituents of food, the uses of which have just been explained. The cereals contain a much less proportion of water, but still the moisture present in oat straw in good condition is as much as 11 per cent of its entire weight. Every 100 lbs. of oat-straw contains ½lb of oil, 1½lb albumen, and 37 lbs of the carbo hydrates, and as a feeding substance it has a greater value than is generally accorded to it. The grain contains 4½lbs. of fatty matters, 9lbs. and 4½lbs. respectively of the albumenoids and carbo-hydrates. The feeding properties of clover hay greatly depend upon the mixture of the various grasses and the amount of clover present in the mixture. Before the crop is at full maturity, or before the seeds begin to ripen, the nitrogen is most abundant, and as ripening proceeds, the nitrogen diminishes, while the proportion of the carbo hydrates increases. It will thus be seen that the analysis of hay must vary greatly according to the stage of maturity the crop has attained when cut, and the condition in which it is secured. Theoretically in the feeding of cattle, hay and turnips should produce results equal to a supply of good oat-straw and turnips, alone with several pounds of linseed cake. It has been estimated that, as an auxiliary to the ordinary food, 7lbs. of oats and 12lbs. of clover hay are equivalent in value, and should each make 1lb. of live increase. In the meantime, oats at 20s per qr of 320lbs. represents £7 per ton; and according to the above scale of comparative values, hay should be worth as an article of food about 82s. per ton, whereas it can be purchased in the market at about 60 per ton. The analyses which have been given clearly show that there is an enormous loss in the conversion of the natural produce of the farm into meat, and many theoretical men are astonished how cattle thrive and fatten as they do upon such food. But still, even those who put their faith to chemistry and its teachings, if possessed of experience gained in the practical school of nature, will readily admit that the results are much better than can be expected, and especially is such the case when the natural food has been produced on good soil, and in high manurial condition. The reason why such substances as straw, turnips, mangolds, and potatoes, which contain little but water and the carbo hydrates, fatten animals at all, is because, as has already been explained, the latter maintain heat in the animal system, and, by assimilation to a limited extent, they may be transformed into fatty matters, and therefore become stored as fat in the body. In these days when the turnip crop is a very uncertain one, and from its uncertainty the expenses connected with the production of beef are high, farmers cannot afford to lie in the arms of Morpheus, but must be ready to take advantage of all the benefits which flow from an increased knowledge of science, and the lessons which practical experience teach. Science teaches us that the food generally served to fattening animals is not of a nature capable of producing the best results in the least time, and it also shows us that if we are aiming to produce flesh and fat at the least cost, and in the least time, it is of paramount importance to have the food of the requisite nature

for those purposes. Seeing that in the natural produce of the farm, oil is scarce, in artificial food it becomes the more necessary ingredient for the early maturing of stock, and it also becomes necessary so that the flesh of our animal be well mixed with fat. In linseed cake the proportion of moisture is only about 10 per cent, or one-tenth of its entire weight, the remaining nine tenths consisting of substances of more or less value as food, and contains from 10 to 12 per cent. of oil, about 28 per cent albumenoids, and from 30 to 36 per cent of the carbo-hydrates. Such analysis clearly shows that linseed cake is a very valuable feeding substance, and from its better digestibility it possesses a value above that of decorticated cotton cake, although the latter possesses on analysis 50 per cent higher than the former. The value of any food greatly depends upon its digestibility, and practical tests have shown that as a feeding substance, decorticated cotton cake is inferior to linseed cake. From the indigestible nature of decorticated cotton cake, eminent authorities have given it as their opinion that as much as seven eighths of its albuminous constituents pass through the animal without being assimilated. Decorticated cotton cake contains a half more nitrogen than linseed cake, or nitrogen equal to 8 per cent ammonia, consequently its manurial value is very great, and if that be taken into consideration, which it deserves to be when estimating its value, then it is worth considering whether it is not susceptible of improvement by grinding and mixing with other substances of a less concentrated nature, and thereby enhance its value as a feeding substance. The preparation of food is a matter of considerable importance in connection with the economical consumption of the turnip crop and the judicious feeding of cattle. The system of cutting straw and pulping roots, which a few advanced feeders have adopted, has much to recommend it, inasmuch as whatever meals are used can be readily mixed with the prepared food which is given in a more presentable form, and not attended by the waste which takes place under the ordinary system; the animals also can the sooner take their food and consequently have more time for rest. In the fattening of cattle generally in this district, I believe the practice of most farmers is to allow a bullock 150lbs. of roots per day, along with straw *ad libitum*. If such a quantity was given along with a very liberal allowance of concentrated feeding stuffs, cattle could scarcely be expected to pay for their fare. But if the supply be reduced to nearly one-half, or a quantity not exceeding 100lbs. per day, along with 4 or 5lbs. of cake or meals, there is a greater probability of a return for both, the natural and artificial food consumed. In many cases when very large quantities of highly concentrated food are given, I am afraid that a direct profit from its consumption would be too much to expect. It is desirable that whatever is given in the form of artificial food, should be given in good condition, and suitably balanced, containing the proper proportions of albumenoids, carbo-hydrates, and oil, so that the process of fattening should be as much hastened as possible. In the meantime, various substances, such as oats, barley, and linseed can be compounded by the farmer in proportions to show an analysis similar to linseed cake, and at less expense than cake; but as farmers generally mix their meals with cold water, a considerable amount of the nutriment is destroyed by that rough and ready process. Meals should be always given dry, or mixed with boiling water, which would be the means of at least partially cooking the food and making it more palatable and more easily digested. In preparing a meal it is desirable to draw the constituents from a variety of sources, because the oats and barley ground into meal, being comparatively poor in albumenoids and oil, would never do to be given alone. In order to increase the feeding value of such substances, it is necessary to add nitrogenous constituents, which can be done by adding bruised linseed or decorticated cotton cake ground into meal. It is to be remembered that the nutritive value of a food does not depend altogether upon the nitrogenous elements or the supply of albuminous compounds present in the mixture, but to a certain extent upon its digestibility and palatability. In compounding a meal, care should be taken not to have too much oil present, as a superabundance would have an injurious effect upon the animal's digestion, and for a feeding bullock possibly 1lb. is as much as can be assimilated in the twenty four hours. As ruminating animals require a certain amount of bulk in their food, it would not do to feed them upon a highly concentrated food alone without a supply of the bulkier kinds, such as turnips and straw. In reference to the comparative values of natural and artificial food, I may mention an experiment which was carefully conducted by Mr. John Milne, of Lathara, Turiff, and recorded in the last published volume of the *Transactions of the Highland and Agricultural Society of Scotland*. The result of the experiment clearly showed that 4lbs. of linseed cake and 5lbs. of cotton cake or maize were equivalent to 10lbs. of turnips. Seeing that by analysis cotton cake is 50 per cent better than linseed cake, a directly opposite result might have been expected. There are many other important matters connected with the feeding and fattening of cattle which claim attention; but, as I have already occupied too much of your time, I shall briefly allude to only a few of them. The most important of these I consider is regularity in feeding, which is the means of preventing restlessness, and is therefore of great consequence. Cleanliness of the byres, and animals should be carefully attended to, and their litter should receive attention. A suitable and even temperature, together with properly ventilated buildings, and an immunity from draughts, are none the less desirable, yes, essential to satisfactory progress. It is unnecessary to mention that in order to secure satisfactory results in fattening, judicious care and treatment are necessary from the day of the animal's birth to bring satisfactory results in *s. a. d.*

—North British Agriculturist.

EXPERIMENTS ON THE SULPHITE WOOD PULP PROCESSES

A CONTRIBUTOR to the *Papier Zeitung* publishes in the number of that journal for the 15th ultimo a communication of which the following is a translation.—

Last week we had a visit paid us by a gentleman who had been several days with Mr. Ekman at Bergvik, and with Mr. Francke at Molndal, Sweden, for the purpose of experimenting; and we are now able, owing to his friendly assistance, to state exactly the result of his visit.

We must in the first instance correct our previous statement with reference to Mr. Francke's boiler, so far that the taps are now different. The taps are not made as usual of cast-iron, but are merely a continuation of the cylindrical boiler with egg ends; indeed the boiler is merely tapered off at the ends, and is constructed without any sharp corners or angles, so that it can be thoroughly well lined with lead; the ends are closed by screwing on brass plates. At each end of the cylinder, just about where the tapering off into egg shape commences, two broad iron bands about 8 inches wide are placed, which latter are carried on two heavy cast-iron rollers 18 inches diameter; these four rollers are supported on cast-iron bearings, and the cylinder revolves slowly on these rollers driven by cog.

The boiler fully lined with lead weighs quite 40 tons; the lead is not attached to the boiler in any way, but forms a boiler of itself inside the iron cylinder; on the inside of the cylinder at distances of about 8 feet apart are introduced brass rings of inch thickness by 2 inches wide in the shape of wedges which keep the lead against the outer iron shell.

Ekman's mill at Bergvik, near Soderham, 350 kilometres from Stockholm, only prepares unbleached stuff, which is worked up by Thompson and Bonar of Ilford, near London. The boilers used here are only 4½ feet diameter and 12 feet long, and are constructed like Labrousse's straw-boilers. Ekman's mills are worked exactly on the same principle as that described in his American Patent No. 21 of 1882.

On the other hand, while Francke and Mitscherlich use lime, Ekman uses magnesia, which he procures in the shape of carbonate of magnesia from Greece and Germany; this magnesia is burnt in the same manner as chalk, by which process it loses its carbonic acid, and is converted into magnesia; this is placed on shelves inside a leaden tower lined out with wood so as to protect the lead, and sulphurous acid gas is introduced passing upwards, water being allowed to trickle down over it, which is partly absorbed, so that at the end of the operation merely a silty mass remains; the boiling with the solution of magnesia and SO₂ is conducted as described.

We think it improbable that Ekman obtains his SO₂ from Siolian sulphur instead of from pyrites.

It seems of importance that Ekman does not cut his wood into pieces like Francke or other cellulose manufacturers, but that he first saws it into planks, and carefully boro out every knot afterwards; it is very easy to distinguish the imperfections in boards, whereas in the small hacked up pieces these are very difficult to detect. These boards are split up still smaller, and then crushed.

We are indebted to this costly preparation of Ekman's stuff for the following results, viz., that his stuff works up quite clean, without using any knotters or strainers. Our informant brought samples of Ekman's and Francke's raw material, and samples of the stuff at all different stages of the process, and the result proved that Ekman's stuff boiled (not bleached) is cleaner and nearly as white as Francke's bleached stuff.

The paper made from Ekman's unbleached stuff, and which we have seen, can be used for the best writings, and is superior to paper which was made from Francke's stuff which was only fit for news; we have also seen paper made from Ekman's bleached stuff which is quite equal to paper made from fine linen.

The principal theoretical difference between the lime and magnesia process is that the gypsum (lime process) is not easily dissolved, and remains in the stuff, whereas the sulphate of magnesia is readily dissolved, and is easily washed out, none of it remaining in the stuff.

We do not know whether the magnesia has any other advantages over the lime, but it would be very interesting if this could be proved by a trial. The cost of Ekman's unbleached stuff at Bergvik is £13 per ton, but the selling price is £20 per ton. It has been proved that, according to the price, Ekman's stuff is better than either Francke's or Mitscherlich's as it comes into the market, we are, however, unable to say whether this is owing to the method of manufacture or to experience.

The French paper manufacturers who visited Bergvik gave a detailed account in the French language, which we now repeat, translated and condensed.

"Result of experiments made at Bergvik in the presence of the undersigned manufacturers, on the 25th and 26th July, 1882. The wood, white pine, was felled in the spring of 1881, and sawn up in autumn into planks weighing 4,395 kilos:—

| | kilos. |
|--|--------|
| There was a loss during storage of planks of | 200 |
| Do. through cutting | 233 |
| Do. through cleaning, dusting and sorting | 332 |
| Making in all a total loss of | 825 |

825 kilos from 4,395 kilos, leaves 3,570.

"This lot of 3,570 kilos was put into 4 boilers, and after being washed in the ordinary potshers, was put up into 18 bales weighing nett 2,875 kilos, (moist weight); on being dried this was reduced to 51.30 per cent dry stuff; another trial, or test in the same way only yielded 48.70 per cent—the last trial seems more correct. Taking the yield at 50 per cent, by splitting the difference, the weight of the dry stuff obtained is 1,437 kilos.—32.68 per cent of the raw wood which contained 21 per cent moisture.—Bergvik, 27th July, '82, signed by 12 gentlemen whose names we cannot decipher, and therefore omit."

The yield of 32.68 per cent boiled unbleached stuff seems low, but if we consider the 21 per cent moisture which it contained, the dry weight would come to more than 40 per cent, but even then the yield is smaller than Francke's or Mitscherlich's; when, however, we consider that the stuff is perfectly clean and free from dirt, impurities, and gypsum, the yield is not really so low in comparison.

Mr. Kramer uses the Mitscherlich cellulose advantageously for printing and lower quality paper.

Mr. Kramer prefers the Mitscherlich cellulose to soda boiled, and says it is tougher; Mr. Pettermann, of Wangen, has compared several samples of paper made from Mitscherlich stuff, and is of the same opinion as Mr. Kramer.

Mr. Kramer washed some of the Mitscherlich stuff in a five-centner engine for two hours, after which he says it worked up very well; and Dr. Doru confirms what Mr. Kramer says and states that he washed some with muriatic acid three quarters of an hour, by which operation the gypsum entirely disappeared, and this stuff then takes the colour very well for papers.

Paper made entirely from Mitscherlich stuff without the admixture of rag is not good, and calenders very badly (that is, a bad surface); Mr. Pettermann holds that it is very advantageous to wash the cellulose with hypo sulphite of soda, which materially assists the sizing; Mr. Kutter would prefer that the Mitscherlich stuff were washed and free from gypsum.

Another article appears in the same journal of the 22nd ultimo on the subject of sulphite wood pulp and soda cellulose, as follows:—

A great deal has been written lately about sulphite wood pulp, but few figures have been brought forward by disinterested people. There is, however, in No. 8 of the *Papier Zeitung*, an interesting description of the sulphite wood manufactory at Korndal, near Gottenburg; and as the figures seem to be given by a disinterested authority, they may be assumed as correct. No doubt a comparison between these and those of the soda-boiled cellulose will prove interesting.

The boilers at Korndal are 7 feet diameter by 40 feet long, and cubical contents of each 1,500 cubic feet; the weight of sulphite stuff (dry) produced from a boiling is 1,800 kilos. These figures do not agree with the patentee's, viz., that the weight of the manufactured article is much larger than that of the soda treated article, for—

Lee's boiler, 4 feet diameter and 10 feet long, contents 500 cubic feet, yields for each boiling 650 kilos. dry cellulose.—1,950 kilos for 1,500 cubic feet.

Sinclair's boiler, 600 cubic feet, gives 800 kilos.—2,000 kilos for 1,000 cubic feet space.

Spherical boilers give about the same result.

Now, one can quite well surmise that the sulphite manufacturers fill their boilers as full as they conveniently can, and that in every boiler a cubic foot holds about the same quantity of wood: from this, it would appear that the sulphite process cannot give a greater yield than the soda process, and it seems, therefore, that this great saving does not exist; the high yield the patentees assumed owing to their having the same as chemically free from water, whereas the soda manufacturers take their weight as it is produced in the process; and this largely assumed yield will be yet more difficult to understand when the result of M. Knosel's experiment proves that by washing and bleaching 25 per cent more weight is lost.

The number of boilings at Korndal in each boiler in 24 hours is 1½ to 2; but as with the soda process three to four boilings are accomplished in 24 hours, so one is enabled to boil double the amount of stuff in the same boiler in the same time; and as the boilers hypothetically contain the same cubical contents, thus for boiling with soda only half the number of boilings is necessary, therefore the cost for soda boilers will be lower, and they stand twice as much strain, as they require no costly lead lining and no expensive arrangements for revolving. The wear and tear in the sulphite process seems considerable, as the lead has to be renewed yearly although of 3 m.m. thickness, and this 5,000 kilos of heavy lining necessitates many other expenses for soldering and repairs.

With the soda process the boilers last for ever, as the soda ley preserves iron; and we have even several instances of boilers which were not tight at first becoming tight after use, as the leaky places become filled up in time with lime and silica incrustations.

Cost of Chemicals.—I much regret that this point is not alluded to in the No. 8 *Papier Zeitung*, as it is of great importance. I will not repeat Mr. Catchside's figures from No. 4 *Papier Zeitung*, as other figures emanating from the inventors vary more than 100 per cent. (See notice in the *Papier Zeitung*, that an English mill which was to have cost £8,000 cost £14,000, and then only turned out two-thirds of the stated or promised production).

Mitscherlich gives the cost of chemicals at 32 marks per 1,000 kilos sulphite pulp; whether this is correct I do not know, although it has been proved that other calculations of Mitscherlich have been too low, yet I will assume his figures to be correct; then from these figures it has been proved that the sulphite process has no advantages over the soda process, for if one recovers 92 per cent of the soda, the charges for 8 per cent of soda with lime, coal, and labour for the recovery would amount to 22 marks per 1,000 kilos of wood pulp, and there is

also the advantage of using the waste heat given off in the burning, but in the sulphite process this recoverable matter, which constitutes half the weight of the wood treated, is totally lost.

There is no account in No. 8 of the recovery by burning in the sulphite process, but in the soda this has been reduced to such a minimum that it can hardly be so little with the sulphite.

Manufacturers who know nothing of the sulphite process are trying it, but they will find out in the end that the soda process is the best.

This also holds good for Esparto grass; and the well-known authority in this matter, Mr. Houtledge, in alluding to a resumé of Knossel's views on the sulphite process, surmised that it promised more than could be realised.

Lee's and Sinclair's soda processes were also very promising, but we know how their results have been carried out, and it is only after ten years' experience and costly experiments that they have been accomplished.

In Sweden no one has followed Ekman's system, and on the other hand lately several soda cellulose manufactories have been erected.—S.—*Paper Maker's Monthly Journal*.

ARTIFICIAL MANURES.

As far back as 1879, a work on Artificial Manures appeared in this country, written by a French chemist, M. Georges Ville, and translated and edited by Mr. Crookes, F.R.S. Few works on agricultural matters have caused more interest. The writer gave his opinions with so much confidence—quoting experiments in proof of the conclusions he had arrived at—that the public were very much carried away, and disposed to take M. Ville at his own valuation. The work was favourably and largely noticed, and we think that the *Field*, amongst other papers, called attention to the remarkable results said to have been obtained by the use of artificials, and also to the statements as to the power of certain plants to obtain supplies of nitrogen direct from the atmosphere.

Quite recently Sir J. B. Lawes has published in the pages of the *Agricultural Gazette* a series of seven articles which will be found in the numbers from January 1st, 1883, in which he subjects M. Ville's statements to a critical examination, and exposes their utter unreliability. The farming public, who are interested in this question, are much beholden to Sir James B. Lawes for having detected these fallacies, which as their principal object was to discredit farmyard manure and to exalt the virtues of artificials, and especially of certain receipts which appear at the end of the book, might, if accepted by English farmers, have led to great losses.

Artificial manures, suitable to the particular soils and crops, are valuable supplements to farmyard manure. But this, as containing all the materials required in plant food though perhaps not always in the exact proportions most necessary, and being made, as a rule, at much less cost than what we pay for artificials, should be for nine-tenths of us our main resource. Instead of our being led away by a will-o'-the-wisp in the form of patent manure, and so induced to continue the wretchedly wasteful methods of manufacture which still too frequently prevail, we should be told how we may improve our practice, and how, by making and keeping our manure under cover, we may secure a concentrated and portable material, which will, if we only have enough of it, render us to some extent independent of artificials. The more we can replace the outlay now made in artificial manures, by outlay in feeding materials which enrich the droppings of animals eating them, the more profitable will be our operations, because we shall get back much of our outlay in the animals, and we shall have a much more permanent manure; for, as the reviewer points out—

"If there is one fact more than another upon which all practical farmers in Great Britain are absolutely agreed, it is that of the lasting properties of farmyard dung as compared with artificial manures; and I may add that the general result of the Rothamsted experiments has not only been to confirm the experience of practice, but even to extend the operation of the dung to a far longer period, than that generally assigned to it."

This sentence was *apropos* of a statement to the effect that the idea that the farmyard manure in an experiment of a M. Ponsard had not been exhausted in one year, whereas the chemical manure had been exhausted, was "contrary to all the known facts." It may be as well to give the quotation from the preface to the French edition referring to this same experiment, as an illustration of the delightfully vague way in which matters, whose value depends upon exactness, are treated:

"M. Ponsard, President of the Agricultural Chamber of D'Ouray, in Champagne, made two parallel experiments on a piece of waste land in one of the most barren districts of a proverbially barren portion of that province. He manured one-half of the ground with about 32 tons of farmyard manure per acre, and the other with about half-a-ton of chemical manure per acre. With the farm manure he obtained about 14 bushels of wheat, whereas with the chemical manure the land yielded about 38 bushels, there being a loss of £19 in the former case, and a gain of £17 in the latter."

If the figures as to profit indicate the general accuracy of the whole, we may pass over M. Ponsard's experiments as absolutely unreliable seeing that, whilst M. Ville tells us that the cost of growing wheat (which, under the present system of agriculture, is 5s. 6d. a bushel) may be reduced to 3s. 9d., he yet would have us believe that thirty-six bushels of wheat realised a profit of £17, equal to 2s. a bushel; and this is, of course, supposing no value for the land, and no expense in its cultivation.

As regards the important question as to the sources of the nitrogen of plants, M. Ville's statements as to the power of plants to derive a portion of their supplies directly from the air is blown to the winds by a mass of facts, the result of actual experiments. M. Ville states that nitrogen is assimilated by plants in three different forms, viz., as ammonia, as the nitrate of some base, and as nitrogen gas; and that it has been ascertained that "crops always contain more nitrogen than the manure supplied to them, and this excess is derived not from the soil, but from the air." Such a positive statement is proved by Sir J. B. Lawes to be absolutely erroneous in every instance. Wheat most nearly, of all our cultivated crops, accounts for the nitrogen supplied in manure. In every other instance where excess of nitrogen above that contained in the manure is said to be derived from the atmosphere, the very opposite is the fact—the manure contains more nitrogen than appears in the crop, and a considerable loss occurs. In the analysis of the soil in which his experiments were carried out, though made with the greatest care no mention is made of nitrogen, but he refers to it as similar to that of Rothamsted as to the nitrogenous matter. Sir J. B. Lawes states that within reach of agricultural crops, the arable soil contains from 10,000lb to 12,000lb of nitrogen per acre; but, apparently M. Ville leaves this out of calculation altogether; and, because he finds more nitrogen in certain crops than was supplied in the manure, jumps to the conclusion that the balance was derived directly from the air. In the case of wheat—which, as has been shown, makes the best use of the nitrogen supplied—it is shown by the reviewer that lowt. nitrate of soda furnishes 17lb or 18lb of nitrogen, and that if every particle were taken up this would suffice for 11 bushels of extra wheat, and he thinks farmers would be satisfied with 6 bushels on an average; and that even in 1863, the year of maximum produce at Rothamsted, the amount of nitrogen in the increase of the experimental crop was considerably less than that supplied in the manure.

As regards beetroot, M. Ville's statement that there is an excess of 114lb. per acre over that furnished by manure, which is derived from the atmosphere, appears to us wide of the mark; and this is actually proved from the experiments he quotes. Thus certain manures without nitrogen resulted in a yield of 14 tons 14cwt. of roots per acre. By adding to the minerals sufficient sulphate of ammonia to supply the respective amounts of 176lb, 220lb, and 264lb, of nitrogen per acre, a respective increase was obtained of 4 tons 6 cwt., 5 tons 14 cwt., and 9 tons 2 cwt. per acre. Now, as the highest increase could not have contained more than 72lb. of nitrogen per acre, and the smallest application of that substance was 176lb, it is evident that, instead of a gain, there is an enormous loss of nitrogen. Another most remarkable statement is that the profit on an application equal to 12 cwt. of sulphate of ammonia, which caused an increase of 9 tons 2 cwt. of beets, was £9 2s. 6d. Numerous other gross blunders, inaccuracies, and contradictions are pointed out. Thus, in one place, we are told of experiments in which artificial manures proved more permanent, and in another lecture that farmyard dung, "owing to its nature and its bulk, necessarily acts very slowly . . . and becomes the equivalent of a large amount of acquired riches."

Perhaps the most amusing part of M. Ville's book—which must be really considered more in the light of a romance of agricultural science than a work dealing in facts—is that in which he criticises Boussingault's farming operations and balance sheets. Discovering a mare's nest as respects the value put on the manure, he takes out balance sheet No. 2, which, with the correction as to the value of the manure, turns Boussingault's modest profits at Bechelbronn, shown in his balance sheet, into a loss. Next by the use of certain artificial manures, crops are to be troubled, and he balance put on the right side to the tune of £525-11-2. Thus is developed balance sheet No. 3, and in a fourth balance sheet the profits are actually increased to £933 4-10.

Sir J. B. Lawes points out many other errors which our limits will not allow us to recognise. Enough has been advanced to act as a warning to our readers not to blindly follow the advice of one who, however well intentioned, is not a farmer, nor scientific man, but is evidently profoundly ignorant of agricultural practice. The season is coming on when artificial manures will be in use. They are, when composed of genuine ingredients, suitable to the crops and the soil, valuable as additions to the manurial resources of the farm; but, whilst we venture money in such aids, let us take care that we get as much as we possibly can from our home materials.—*Field*.

IRRIGATION WORKS IN SPAIN.

THE brochure by Sr. D. Andrés Llaurodo, from which was translated the account given in a preceding number of the *Journal of Forestry*, on irrigation works in the south of France, was noticed in the *Journal of Forestry* at the time of its publication. It has subsequently been printed in *extenso* in the Spanish *Revista de Montes*, and it has thus again come under notice.

In a paper which was published in French in the *Annales des Ponts et Chaussées*, and which was subsequently reproduced in German, Bohemian, Italian, Portuguese, and English, and in Russ—the last-mentioned translation having by direction of the Government at St. Petersburg appeared in all the official agricultural journals of the Empire—Sr. L. had shown that extensive irrigation undertakings can only be executed with profit to the promoters and benefit to the general interests of the country when aid is given by the State, and when in addition to the direct returns anticipated by the Treasury, there is taken into account the direct returns brought to it by the thousand and one small meadows from what may be called sedimentary wealth produced from a thousand transformations of the produce and works connected therewith. And in

view of the Government having announced the contemplated inauguration of a legislative company, organized for the development of the material interests of the country, and the Minister de Fomento having intimated a welcome proposal to submit soon to the Cortes a draft bill likely to stimulate the execution of extensive works for the utilization in agriculture of water now running to waste, Sr. Llaurodo deemed it opportune to bring under the consideration of the Minister in the first instance, and in belittling time under the ordeal of public discussion, some general estimates suggested by his friendly interest in the scheme, and sundry facts and important documents whereby he hoped might be supplied some aid in acquiring a correct knowledge of works already executed in connection with irrigation and sanitary and agricultural improvements,—and thus to supply evidence of the urgent necessity there is for doing what both the Government and public opinion admit that both the importance and the justice of the measure required should be done in the matter.

Passing over, for convenience, details of arrangements of a legislative character, which had successively been required and made in the country, the author sought to stimulate the spirit of the projected association by giving details of what had been realized in connection with the greater work of canals and work of irrigation in France.

The author then states in regard to Spain:—"Neither the arrangements which were prescribed by Arts. 8, 11 and 12 of the Law of 20th February 1870, nor those modifying these which were prescribed by Arts. 195, 197, and 198 of the new Law of 13th June, 1879, have been able to do anything conducive to the realization of the purpose of the legislature, as without boldly facing the difficulties of the case, they only present ephemeral and inadequate provisions, establishing at the same time antagonism between interests which it should be the business of the State to reconcile."

The Government has estimated the Imperial Aragon Canal has cost, and will yet cost, the Public Treasury—and although at first sight the balance drawn, presents many of the features of an onerous burden—it is impossible to avoid perceiving, when we proceed to analyse it a little, that the result satisfactorily repays with usury the great sacrifices imposed upon the State by the execution and maintenance of that work.

"A short time since, while the Count of Tereno was Minister de Fomento, there was submitted for the consideration of the Cortes a draft law relative to subventions to canals and reservoirs, in which the Art. 2 determined that the aid to be given by the State should be the third part of the estimated expense of the undertaking comprising the digging of principal and secondary aqueducts for the convenient distribution of the irrigation. The project was relegated to the keeper of the Archives, and abandoned in despite of the intelligent desire of the Minister being stated and supported by a reference to the empires for its being thoroughly discussed, and we cannot at present secure for agriculture waters which are now running to waste in the basins of some of our rivers, while crops are manured and diminished, if not entirely lost, through protracted droughts."

Sr. Llaurodo then gives the details of observations made by him in France, to which reference has been made, and goes on to say, in regard to what he considers practicable and desirable in Spain:

"What we should do is to combine with our own practice the French principle of giving aid to enterprises connected with agricultural improvements, including amongst these the construction of canals and reservoirs for irrigation, the improvement of moist and unhealthy grounds, the draining of marshes and stagnant water, and the submerging even of vineyards as a means of combating the plague of the phylloxera."

"In doing so the aid of the State, in accordance with conditions which we shall state immediately, should consist of terminable loans to be repaid by instalments along with the annual interest. Guarantees of interest and capital invested in such undertakings, direct subventions in money, or it may be the entire construction at the expense of the State of works presenting exceptional difficulties. The advances within a fixed limit determined by law made from a special charter or credit established in the Ministry of Public Works, should bear, in the meantime, an interest of 3 per cent, and be repaid in a period of thirty years. A special regulation should determine the organization and practices of this fund, so as to avoid difficulties presented by a law of 17th July 1850, relating to draining, and modifying this in the new project, so as to make more accessible to agriculturists the benefits which this offers. To the associations or companies which with the authority of the Government may be organized with a view to the execution of works such as have been referred to, there might be conceded by the State, under conditions which will be stated presently, a guarantee of interest on the capital which they invest in the works. This guarantee of interest should be conceded through an order given by the Minister of Public Works, after consultation with the Council of State, confirmed by the Minister de Hacienda."

In the constitution of the Company should be embodied a stipulation to make a special contribution annually for the establishment of adequate amounts to be exclusively employed in payment of the interest and annual instalments towards the repayment in thirty years of the capital specified in the proposal approved by Government, which contribution must be altogether independent of what may be required to cover the expenses of administration and of the maintenance of the works.

If, in the course of executing the works, as frequently occurs in works of this kind, it shall become manifestly the case that the sum sanctioned is inadequate, the State guarantee may be so extended to an excess, if justified, of not more than half of the amount first guaranteed. This new loan, which the Syndicate may procure in excess of that at first granted, must in like manner be repaid within thirty years.

"In any case in which the contribution for meeting the expenses of the first establishment of the Company, and in which the other

resources reckoned on by the Syndicate independent of those destined for the administration and use of the water and the maintenance of the works, may prove insufficient to carry the normal interest and repayment of the authorized loans, the State may give to the friends of the Syndicate in the form of advances preferential terminal loans the amounts necessary to complete the annual provision for the aforementioned payments; and these preferential loans granted by the State should bear a simple interest of 3 per cent.

"For security of repayment of these preferential loans together with that of interest on them all, the resources which are available for meeting the expenses of administration and maintenance, together with those for the first establishment of the Company, should be devoted entirely to the repayments of those advances made by the State, until the Syndicate obtain a full discharge."

"If the entire completion of the works require an outlay exceeding the maximum amount of the loans guaranteed under the conditions which have been stated, then, but then only, can the Syndicate obtain from the State a supplemental guarantee under an obligation to appropriate either through an increase of the normal contributions, or by some other means, sufficient funds to pay the interest and liquidation in thirty years of the new loan, and without prejudice to the provision made for the payments of the previous loans."

"If at the expiry of the time fixed by the order, a decree which conceded the guarantee of interest, the work be not entirely completed, the Minister of the department may order them to be completed at the charge and expense of the Company; in which case the State shall reimburse itself the expense incurred by it in excess of the expenses specified in the original proposal limit and the Minister of Public Works, after hearing the Syndicate, fixing the corresponding increase of contribution to be made."

"With respect to companies, the Concessionaries of works, which we have suggested should be comprised in the law of State aid, we would establish the following basis:

"Concessionaries may obtain from the State a guarantee for the interest of the capital which they invest in the works. The guarantee shall be in force for fifty years, and should comprise interest and repayment of capital in that time—for which purpose there should be specified in the decree of concession the capital actually invested in the works in excess of subvention for work executed—and for legitimate expenses incurred by the Company obtaining the concession. The guarantee should in no circumstance exceed 4 65, inclusive of repayment of the capital invested."

"When the whole of the clear proceeds obtained through the execution of the works shall exceed 6 per cent of the capital actually invested in the works—after deduction of the whole gross amounts of the subventions of every kind granted—the excess, at what time soever it may occur, shall be appropriated to the repayment of capital and interest at 3 per cent of advances made under title of guarantee of interest. And whenever the State has been repaid its outlay, the excess shall be divided in equal parts between the public Treasury and the Concessionaries."

"A special regulation should determine all that relates to the guarantee of interest conceded by the State to the repayment of the advances which it may have made—to the partition of the benefits secured and to the form in which the Concessionaries shall meet with the intervention of the Government. 1. The burden of the expense of first establishment. 2. The annual expense of the maintenance of the works, and the exploitation of the enterprise. 3. The dues and taxes. There must not be comprised in this annual expenditures for interest any repayments of the loans which the Concessionary may have obtained for the completion of the works—in case of the insufficiency of the capital guaranteed by the State. On the other hand, there must be included in these annual expenditures the interest of the security which the Concessionary had to give when such a deposit had to be made."

"The general question of the first establishment should be determined provisionally at the time at which the works are completed, and definitely five years thereafter, without which being done, in no cases can the Concessionary pretend to any augmentation of the maximum capital guaranteed by the State in the deed of concession. When the period of five years has expired, notwithstanding they may not have made any application, the Concessionary may be authorized by means of a decree, the information having previously been given to the Council of State, to add to this account all the expenses incurred in the execution of the works which have been acknowledged and declared as pertaining to the first establishment, it being understood that this augmentation can only have reference to the calculation made of the unforeseen excess of which mention has been made."

"We would likewise have it determined in the law of State-granted assistance, that the State would grant subventions to undertakings, and associations, giving themselves to the execution of works such as have been indicated, without prejudice to resources which may be appropriated to the same object by provinces and municipalities interested in the execution of the work. These subventions might be conceded by the State in the form of works of equivalent value executed directly by the public administration."

"If there be occasion for it, the declaration of public utility might embody in it authority for the execution by the State of the works spoken of in the supposed law. This authorization should in no case be carried into effect until those who are interested in the work have subscribed in due form a promise to organize a responsible Syndicate to secure the maintenance of the works so executed, and to make to the public treasury an annual payment sufficient to cover the interest and repayment of the portion of the expenses which would devolve upon them and the final completion of the project."

"The deed of declaration of public utility should fix the amount and duration of these annual payments and settle at the same time the proportion in which should be paid by the

Syndicate and by the State the annual dues till the completion of the time in which the whole amount advanced must be refunded.

"Finally, the State might concede pecuniary compensation to proprietors of marshy lands, which, under a declaration of insolvency, in the terms prescribed by law, have completed works within a time prescribed in a legal injunction to proceed to the draining and healthful amelioration of these lands.

"Such, in conclusion, are the provisions which we consider the French Government should make in the new law which it is preparing for the settlement of this financial participation of the State in undertakings connected with agricultural improvements. But before closing our remarks it occurs to us to ask the Minister de Fomento, in Spain—are such works connected with agriculture of less importance in our country than in that of an adjacent nation? Without fear of mistake we have no hesitation in believing them to be of much greater importance here, and though we admit that the Spanish treasury cannot undertake such sacrifices as may easily be borne by the French treasury, we firmly believe that it is evidently necessary that they should advance on like lines, slowly if you will, but without turning aside from the object or losing sight of the end which leads to the prosperity of our agricultural districts. Projects of the nature here treated of cannot be elaborated impromptu, or carried out without consideration, and in order to adapt them to the requirements and conditions of a country, they require the concurrence of much intelligence, with the aid of much action. If the Minister de Fomento takes the work in hand, leading to the initiation of it his weight and influence, and if political changes do not prevent Sr. Alberola seeing from his ministerial department to the carrying out of the promotion by this means of the prosperity of our agricultural districts, he may rest assured that he will in all time coming possess a just title to the glory of the work initiated in these regions by the Government of which he is a member."

The treatise is dated 6th January, 1882.

JOHN C. BROWN.

Journal of Forestry.

A NOTE ON SAP*.

By PROFESSOR ATTFIELD, F.R.S.

BENEATH a white birch tree growing in my garden, I noticed, yesterday evening, a very wet place on the gravel path, the water of which was obviously being fed by the cut extremity of a branch of the birch about an inch in diameter and some ten feet from the ground. I afterwards found that exactly fifteen days ago circumstances rendered necessary the removal of the portion of the branch which hung over the path, four or five feet being still left on the tree. The water or sap was dropping fast from the branch, at the rate of 16 large drops per minute, each drop twice or thrice the size of a "minim," and neither catkins nor leaves had yet expanded. I decided that some interest would attach to a determination both of the rate of flow of the fluid and of its chemical composition, especially at such a stage of the tree's life.

A bottle was at once suspended beneath the wound so as to catch the whole of the exuding sap. It caught nearly five fluid ounces between eight and nine o'clock. During the succeeding eleven hours of the night forty-four fluid ounces were collected, an average of four ounces per hour. From 8-15 to 9-15 this morning very nearly seven ounces were obtained. From 9-15 to 10-15 with bright sun-shine, eight ounces. From 10-15 until 8-15 this evening the hourly record kept by my son Harvey shows that the amount during that time has slowly diminished from 8 to a little below 7 ounces per hour. Apparently the flow is faster in sunshine than in shade, and by day than by night.

It would seem, therefore, that this slender tree, with a stem which at the ground is only 7 inches in diameter, having a height of 39 feet, and before it has any expanded leaves from whose united surfaces large amounts of water might evaporate, is able to draw from the ground about 4 litres, or seven-eighths of a gallon of fluid every twenty-four hours. That at all events was the amount flowing from this open tap in its water system. Even the topmost branches of the tree had not become, during the fifteen days, abnormally flaccid, so that, presumably, no drainage of fluid from the upper portion of the tree had been taking place. For a fortnight, therefore, the tree apparently had been drawing, pumping, sucking—I know not what word to use—nearly a gallon of fluid daily from the soil in the neighbourhood of its roots. This soil had only an ordinary degree of dampness. It was not wet, still less was there any actually fluid water to be seen. Indeed, usually all the adjacent soil is of a dry kind, for we are on the plateau of a hill 265 feet above the sea and the level of the local water reservoir into which our wells dip is about 80 feet below the surface. My gardener tells me that the tree has been "bleeding" at about the same rate for fourteen of the fifteen days, the first day the branch becoming only somewhat damp. During the earlier part of that time we had frosts at night and sunshine, but with extremely cold winds during the days. At one time the exuding sap gave, I am told by two different observers, icicles a foot long. A much warmer, almost summer, temperature has prevailed during the past three days and no wind. This morning the temperature of the sap as it escaped was constant at 52 F., while that of the surrounding air was varying considerably.

The collected sap was a clear, bright water-like fluid. After a pint had stood aside for twelve hours, there was the merest trace of

a sediment at the bottom of the vessel. The microscope showed this to consist of parenchymatous cells, with here and there a group of the wheel-like or radiating cells which botanists, I think, term spherocrystals. The sap was slightly heavier than water, in the proportion of 1,005 to 1,000. It had a faintly sweet taste and a very slight aromatic odour.

Chemical analysis showed that this sap consisted of 99 parts of pure water, with 1 part of dissolved solid matter. Eleven-twelfths of the latter was sugar.

That the birch readily yields its sap when the wood is wounded is well known. Phillips, quoted by Sowerby, says:—

"Even afflictive birch
Cursed by unlettered youth, distils
A limpid current from her wounded bark,
Profuse of nursing sap."

And that birch sap contains sugar is known, the peasants of many countries, especially Russia, being well acquainted with the art of making birch wine by fermenting its saccharine juices.

But I find no hourly or daily record of the amount of sugar-bearing sap which can be drawn from the birch, or of any sap from any tree, before it has acquired its great digesting or rather developing and transpiring apparatus—its leaf system. And I do not know of any extended chemical analysis of sap either of the birch or other tree.

Besides sugar, which occurs in this sap to the extent of 816 grains, nearly an ounce and a half per gallon, there are present a mere trace of mucilage; no starch; no tannin; 3½ grains per gallon of ammoniacal salts yielding 10 per cent of nitrogen; 3 grains of albuminoid matter yielding 20 per cent of nitrogen; a distinct trace of nitrites; 74 grains of nitrates containing 17 per cent of nitrogen no chlorides, or the merest trace; no sulphates; no sodium salts; a little of potassium salts: much phosphate and organic salts of calcium; and some similar magnesian substances yield an ash when the sap is evaporated to dryness and the sugar and other organic matter burnt away, the amount of this residual mineral matter being exactly 50 grains per gallon. The sap contained no peroxide of hydrogen. It was faintly, if at all, acid. It held in solution a ferment capable of converting starch into sugar. Exposed to the air it soon swarmed with bacteria, its sugar being changed to alcohol.

A teaspoonful or two of, say, apple juice, and a table-spoonful of sugar put into a gallon of such rather hard well-water as we have in our chalky district, would very fairly represent this specimen of the sap of the silver birch. Indeed, in the phraseology of a water analyst, I may say that the sap itself has 25 degrees of total, permanent, hardness.

How long the tree would continue to yield such a flow of sap I cannot say. Probably until the store of sugar it manufactured last summer to feed its young buds this spring was exhausted. Even within twenty-four hours the sugar has slightly diminished in proportion in the fluid.

Whether or not this little note throws a single ray of light on the much debated question of the cause of the rise of sap in plants, I must leave to botanists to decide. I cannot hope that it does, for Julius Sachs, than whom no one appears to have more carefully considered the subject, says, at page 677 of the recently published English translation of his text-book of botany, that "although the movements of water in plants have been copiously investigated and discussed for nearly two hundred years, it is nevertheless still impossible to give a satisfactory and deductive account of the mode of operation of these movements in detail." As a chemist and physiologist myself, knowing something about capillary attraction, exosmosis, endosmosis, atmospheric pressure and gravitation generally, and the movements caused by chemical attraction, I am afraid I must concur in the opinion that we do not yet know the real ultimate cause or causes of the rise of sap in plants.

INCUBATORS VS. HENS.

WHETHER there is more profit in artificial hatching than by the services of setting-hens is an unsettled point, for everything depends on the management in either case. That there are good, reliable incubators is a fact, but that "a child can manage them," as is claimed for some, is not established to the satisfaction of many adults who have engaged in such work. The advantages in favor of incubators are that chicks can be hatched at any season, the danger of vermin is lessened, and cleanliness is facilitated by the method. By early hatching, chicks come into market to sell at high prices and the pullets that may be kept over will lay in the fall and through the winter. The disadvantages are, the possibility of danger from oil lamps that are kept continually burning, and the liability of accident, or irregularity of heat, which may destroy all the eggs. A slight accident to an incubator holding several hundred eggs, at a time when eggs are scarce, occasions a heavy loss, and one or two occurrences of such character rather weakens the faith of the operator. It is better, therefore, if large numbers of chicks are to be hatched, to use several small incubators, in preference to a single large one, for then an accident to one incubator will not occasion an entire loss. No matter how well they may be regulated experimenters will have to watch them carefully, as the weather, turning the eggs, and providing moisture call for regular and prompt attendance at certain periods. Some incubators are heated by gas, some by projections of the stove-pipe, and others by large quantities of hot water. Nearly all of them will hatch, by prompt attention and management, but that they bring forth sixty per cent, as claimed, cannot be depended on. After the

* Read at a meeting of the Pharmaceutical Society.

chicks are hatched they are reared in brooders, which are heated in several ways, generally with hot water, the heat being appreciated by the chicks when it is above them, as few survive when the heat comes from below.

In managing the hens, however, the nests should be placed in warm locations in winter and cool places in the summer. If the flock is large the hens will commence setting at different periods, and an advantage may be taken of hatching by using the following plan: Suppose, on the 1st day of April eggs are placed under a dozen hens, as all can be set at one time by keeping those that get broody before the others a few days, and suppose after the lapse of ten days, a second dozen are set; and we will further suppose the breeder to continue the practice by placing eggs under all the broody hens on the same day, when a sufficient number is ready. Now, we go back to our point: when the first dozen have finished hatching, give all the chicks to as few hens as can properly carry them, and take eggs that are under the second lot, and place them under the remaining number in the first lot. Then reset the second lot with fresh eggs. We can by that method keep each hen at work four and half weeks, and two hens will hatch three broods. We give the above as a supposition. It is entirely practicable, and also profitable, and with the same care and management as is required for incubators will give much better results.

The hens and incubators may be managed together by placing eggs in the incubator every day or two, and when the chicks are hatched give them to the hen to be cared for. This will save valuable time on the part of hens, and will enable the breeders to raise a large proportion of chicks. We have no doubt that many of our breeders dread the care of the chicks more than the fear of bad hatches, but the hens will assist the incubator in that respect. —*New Southern Poultry Journal.*

CINCHONA.

CINCHONA: YARROW LEDGERS' ANALYSES.

WE learn that the last mail brought out the results of further analyses of Yarrow ledger bark from 5½-year-old trees by Dr. Paul of London, and we feel, sure our readers will agree with us that they are simply splendid, especially No. 5—14.50 per cent of crystallised sulphate. The Superintendent of Yarrow has sent down 100 lb. of ledger bark from trees thinned out, and, as a test of what it will fetch in the local market, Messrs. Somerville & Co. have been instructed to sell it on Mr. Symons' average analyses of 5.7 per stem and 4.17 per branch bark. The result of sale will be duly reported. With Dr. Trimen's report and such encouraging results as we are now able to place before the public, there should be no hesitation about extending the cultivation of ledgers. The analyses are as follows:—

ANALYSES OF YARROW LEDGER BARK FROM 5½-YEAR-OLD TREES.

| Number of Samples. | Crystallized Sulphate of Quinine. | Quinidine. | Cinchonidine. |
|--------------------|-----------------------------------|------------|---------------|

Analyzed March 1883.

CALISAYA VERDE AND MORADA.

WE are very glad to hear of the great success that has attended the introduction of this valuable seed into Ceylon from two such different altitudes as our two correspondents refer to, one being situated at 5,200 feet the other at a very much lower elevation, and we trust that the plants will continue to thrive and grow into large proportions. If they have the great robustness attributed to them, together with anything like the high percentage of quinine that ledgeriana has, they will indeed prove a mine of wealth to their fortunate owners. As Mr. Ffanshawe says, a tree that will thrive at a low elevation with a rich bark is the thing

wanted, and *Verde* seems to supply that want. As regards its probable size in Ceylon it is impossible to draw inferences from what takes place in America. The whole of the *Calisaya* tribe grow to far larger proportions in their natural homes than they do with us, and the probability is that the same things will occur with *Verde* and *Morada*. Markham's reference to these varieties may not be uninteresting to our readers. He says:—

"Girond and Martinez told me that there were three kinds of *Calisaya* trees, namely, the *Calisaya fina* (*C. Calisaya*, *avara* Wedd.), the *Calisaya morada* (*C. Boliviana* Wedd.), and the tall *Calisaya verde*. They added that the latter was a very large tree without any red colour in the veins of the leaves, and generally growing far down the valleys, almost in the open plain.

"A tree of this variety and yields six or seven quintals of bark while the *Calisaya fina* only yields three or four quintals; and Gironda declared that he had seen one that had yielded ten quintals of *tabla* or trunk bark alone."

A quintal is more than a hundred pounds, so it will at once be seen that these trees grow to enormous proportions in South America and we cannot possibly expect such results here. If they grow to twice the size of ledgers at the same age, and thrive as they apparently do equally well at 5,200 ft. as at very low elevations, they will unquestionably prove themselves by far the most valuable of all the varieties of cinchona. —*Times of Ceylon.*

ATTEMPTED MONOPOLY OF LEDGERIANA BY THE DUTCH.

THE Dutch, as everybody knows, claim the credit of having been the first to introduce and acclimatise in the East the variety of cinchona now known as *Ledgeriana*, the bark of which is believed to be richer in quinine than that of any other. Seeds obtained from Bolivia were carried to Java, and planted in the Government gardens there under the care of Mr. Van Gorkom. After the plants had been thoroughly established there, seeds and cuttings obtained from them were not only distributed amongst planters in Java, but also, with the courtesy usual amongst botanists, they were sent to the Superintendents of Botanical Gardens in India, Ceylon, Jamaica, and other tropical colonies, as well as to the Royal Gardens at Kew, and the result has been, as our columns have testified, that this valuable species has been successfully established in almost all British possessions where cinchona is growing, and in Ceylon, at any rate, there is no difficulty in obtaining an ample supply of "Ledger" seed, locally raised, as the following from one of the latest papers to hand sufficiently proves:—

A planter declares his preference for seeds taken from selected trees in the neighbourhood, some of which are nearly six years old, and explained it thus: "There appears to be a general belief that ledger plants raised from seed cannot be relied upon to come up true to type; however true this may be in regard to imported seed, our experience certainly is, that with seed carefully harvested from selected trees of the true ledger type, the plants may be relied upon to come up true to type."

Moreover, Messrs. T. Christy and Co. recently received from their agent in Bolivia a consignment of ledgeriana seed taken from the same district where Mr. Ledger obtained his original supply, and these are in course of distribution throughout the East and West Indies. Under these circumstances, the policy enunciated in the enjoined paragraph from the *Batavia Dagblad* is not only churlish, but it is utterly futile, and amounts, in fact, to "shutting the stable door after the steed has been stolen"; but, at the same time, the action in question is eminently characteristic of the Dutch Colonial Government with its old-fashioned tendency to monopolies. Our Java contemporary says:—

"The scheme of selling by auction *Ledgeriana* cinchona seeds at the Government plantations here to British India planters, for whom they have more value than for those in Netherlands India, taking into account the fact that this variety of cinchona, the best existing, is most common here but is very rarely met with in British India, has justifiably drawn forth protests against it from all quarters. The scheme is objectionable in the interest of both the Government and the Java cinchona planters. By carrying it out, the Government would be killing the goose which laid golden eggs. Every catty of these seeds distributed throughout Java represents a future cinchona plantation, yielding a permanent revenue, direct and indirect, to Government. Every catty of them forwarded to British India yields only a handful of coin. Scandalous misuse of the liberality of Government by a few of

the planters here, who sold in foreign countries the seeds supplied them gratis for extending their plantations, has, in addition to the needs of the Treasury, caused the Government to hesitate on the good road hitherto followed. It strikes us that to prevent misuse of liberality, nothing would be more effectual than to give away seeds only on condition that if the latter cannot be accounted for by a certain number of seedlings in each nursery on a liberal percentage, the applicant will have to pay a high price for seeds not thus accounted for. So long as private estates do not yield seeds, and are neither extensive nor far apart, such control is not impracticable. We have since heard with pleasure that the scheme for selling cinchona seeds by auction has been postponed for the present."—*Planters' Gazette*.

CACAO.

COCA.

THE medicinal properties of this remarkable plant have lately attracted considerable attention. Its well-known property of stimulating the action of the heart and digestive organs has recently been turned to account in the United States in the treatment of dipsomania, and of the habit of opium eating, laudanum drinking, or sub-cutaneous injection of morphia. There seems no reason, also, why it should not be used to cure the habit of taking chloral. In all these cases it is a stimulant action which is required, and this coca possesses, while it does not produce any deleterious after-effects. Some remarkable results have been obtained by its use, more especially in cases of indigestion, which are entirely cured by this drug, and which lead to the hope that the leaves may soon be in extensive demand. A few cases illustrating these results we quote from a pamphlet recently issued by Messrs. Christy and Co., of 155, Fenchurch-street, who are the importers of the coca. These are genuine cases, taken from various medical journals of good repute, and not mere advertisements:—

"*Coca in dipsomania*.—I have employed this drug as a tonic stimulant in conditions of exhaustion, regardless of the cause. In a case of exhaustion associated with consumption, its effects are very pleasant; it prolonged life, and made it more tolerable. But it is in the alcohol habit that I noticed most remarkably its benefits. It is an invaluable aid to the unfortunate who honestly desires to refrain, but who has not sufficient strength in himself to do so. There are cases in which the entreaties of wife and children, super-added to the exhortations of the physician, are of no avail in strengthening resolution. It is in these that coca is most effectual. It is *par excellence* the remedy in dipsomania.—E. A. ANDERSON, M.D., Wilmington, N.C."

"*Coca in opium habit*.—An unmarried man, æt. 27, contracted the opium habit five years previous to using the coca. Had become a great slave to morphia. June 1879, I put him upon coca. He ordered three pounds at the beginning. In October following I met him, and he assured me that he was entirely relieved of the habit and had one pound of his medicine left.

"One word as to my mode of using the coca. As stated above, it is capable of stimulating to any given extent. Now my plan has been to begin with a drachm dose of the fluid extract, just when the desire for the opium or whisky is quite urgent, giving it in a little water. If this does not produce sufficient stimulus to take the place of the accustomed drug, I repeat in thirty minutes, and so on. In this way I soon find the required dose.—W. H. BENTLEY, M.D., LL.D., Valley Oak, Ky."

"Allow me to call your attention to the fluid extract of coca leaves as a painless antidote to the opium habit. I have been a victim of it for twenty-three years, and was always on the look-out for an antidote. Finally, my attention was called to the above extract by W. J. Chenoweth, M.D., of this city. I commenced taking fluid extract coca; I kept myself under its influence for about two weeks, at the end of which time I found I could not take the smallest dose without it making me sick, and to my astonishment found myself entirely cured. My only object in writing this letter is to call the attention of the profession to it as a painless antidote.—Geo. Leforger, M.D., Decatur, Ill."

"M.T.P. had for several years taken large doses of laudanum several times a day for what he called 'disease of the stomach.' Was always complaining, and was low-spirited, sallow, poor, and a dejected lifeless-looking creature generally. He often took as much as a pint of the tincture of opium per week, and suffered intensely when without it even for a short time. As he said, his

disease returned as soon as the laudanum gave out. I told him I at last had found a cure for his 'stomach disease,' and ordered the coca to be taken in drachm doses as often as he felt the disease returning, or whenever he felt that he could longer do without the laudanum. He used it frequently for two or three days, but gradually lessened the dose and frequency until cured. Since his cure he has rapidly improved in health and strength, both mental and physical; in short, he is a new man.—Dr. P. R. HENDERSON, in *Louisville Medical News*."

"A lady who had taken xvi grs. of morphia per diem, relinquished the habit, but within two days suffered intensely from insomnia, restlessness, vomiting, and prostration. After the second tablespoonful dose of fl. ext. coca, the pulse fell from 115 to 85, and all her symptoms were marvellously improved. On the following day she ate, digested, and felt well. The coca being continued in smaller doses, within a short time she was entirely cured.—St. Louis Clin. Record, Oct. 1880."

Mr. X. Y. had been addicted to the habit of taking sulphate of morphia for about five years, commencing with one-eighth of a grain for lumbago, changing it from internal to external application (hypodermically over the lumbar region), and gradually increasing the quantity until he reached the enormous dose of twenty-five grains as a maximum, three to four times a day. . . . I started him with the allowance of three twenty-grain doses of morphia, to be taken with a drachm of coca. In a week his morphia allowance had decreased to ten grains a-day, and his dose of coca increased to one-half ounce, and now, three weeks after commencing this treatment, the morphia has been entirely suspended.—H. F. STIMMEL, M.D., Chattanooga, Tenn."

The only obstacle that seems to stand in the way of the extensive use of coca, appears to be the difficulty of obtaining the leaves in the fresh state, since, unless very carefully dried, they lose their properties in six or eight months. Those who grow coca will therefore find it advantageous to employ some method of preparing an extract, or tincture, or beverage of the leaves from the fresh plant, as preparations so made will keep the properties of the plant unaltered for a very considerable length of time. When the leaves are exported they should be picked as soon as fully developed, dried carefully and packed in hermetically-sealed tins; dryness and exclusion of air during the voyage being absolutely necessary.

FORESTRY.

TRAINING FOR THE FOREST SERVICE IN PRUSSIA.

ONE of the first utterances of the *Journal of Forestry* was in advocacy of the organization of a School of Forestry in Britain. Six years have passed; but this has not yet been effected. The subject has, however, been formally brought under the consideration of the Corporation of London by the Superintendent of Epping Forest, and before the India Council by the Society of Arts; it has engaged the attention of the Principal of the Royal Agricultural College of Cirencester; and it has, for upwards of five years engaged the attention of the Council of the Arboricultural Society of Scotland. Of the membership of this Society, numbering well nigh 800, the great majority appear to be foresters and assistant foresters; of seventy candidates admitted to membership at the last general meeting, fifty were assistant foresters; and many of the members of the English Arboricultural Society are practical woodkeepers. With the interest thus manifested in forest management, some information in regard to the course of training followed by foresters in Prussia may be acceptable.

The following details of the requirements for employment and promotion in the forest service in Prussia, are given in the *Bestimmungen über Ausbildung und Prüfung für den Preussischen Staatsforstverwaltungsdiens* (Requirements for the Education and Examination of Officials in the Prussian State Forest Service).

No one can be received into the Forest Service if he does not satisfy the following conditions:—

1. "He must have obtained a diploma of completed study in a gymnasium of the German Empire, or in a *realschule*. 2. Be not above twenty-two years of age. 3. Have no bodily infirmity which would unfit him for the forest service. 4. Be of good conduct. 5. Give proof of possessing sufficient means to meet the expense of preparation for the work.

"This preparation commences with practical work done in the forest under the direction of an *Oberforster* during at least seven months generally from October to April.

"The design of these preliminary exercises is to make the aspirant, acquainted with work of exploitation, and, with the principal kind of trees, to make him practically acquainted with silviculture, with the surveillance of woods, and the police of the chase, and at the same time with land-surveying, all of which are things which lie at the foundation of his subsequent theoretical studies.

"To be appointed a *Forst-Beisitzer*, or forest-aspirant, an application must be made to the *Forst-Meister*, or to the conservator of the administrative circuit; this application must be transmitted by the *Oberförster*, to whom the pupil desires to be attached.

"The papers to be supplied are five in number.—1. The diploma of study from a gymnasium or *realschule* of the first class. 2. Certificate of birth or baptism. 3. A medical certificate. 4. If the aspirant do not pass directly from the gymnasium to the service, a certificate of good conduct from the time of his leaving the gymnasium. 5. An engagement by the father or guardian of the aspirant to provide for the maintenance of him during at least seven years.

"Further the *oberförster* must supply special information in regard to the family and person of the aspirant: and if there be nothing to hinder the aspirant being accepted, he receives his appointment from the inspector or the conservator. These have a reserved right to appoint the aspirant to another *oberförster* than the one he has chosen, and even to remove him during the time of his preparation, after having referred the matter to the Minister of Agriculture, Domains, and Forests.

"If the aspirant on trial prove not quite satisfactory in the triple point of view—physical, intellectual, and moral, the *oberförster* addresses a report to the *Forst-Meister*, and to the conservator, who judge whether the aspirant should continue his studies: in case of a difference of opinion between them, the minister decides.

"This stage passed, the *oberförster* delivers to the candidate a certificate testifying to the time spent in this stage, and to the work done. This certificate confers on the aspirant the title of *Forst-elve*. To continue his studies, the forest pupil should follow for at least two years and a-half the course of study of a school of forestry, or of a forest institute annexed to a university; those who may desire to follow that pursued in another school than those of Eberwald and Münden, should previously assure themselves from the office of the minister that the time spent by them at this school shall be reckoned equivalent to the studies prescribed by the regulations; and further, they are required to study all the subjects comprised in the programmes of these said schools.

"These forestal studies completed, and, at latest within six years after the commencement of the preparation, the pupil addresses to the minister an application to be admitted to the examinations, and attaches to this the following papers: 1. A *curriculum vite*, or history of his previous course of life, entirely in his own handwriting. 2. The diploma of study in a gymnasium or *realschule*. 3. The certificate of being a forest pupil; 4. The certificate of his having attended the course of study in a school of forestry or in a university. 5. A certificate that the pupil has taken the required part in works of land surveying and the preparation of charts at the schools of forestry, or at the university. 6. A chart prepared by the hand of the candidate of some royal forest of at least 500 hectares, on the scale of $\frac{1}{25,000}$ and this chart requires to be accompanied with an attestation that the work has been done entirely by the pupil.

"The design of the examination is to make it be seen that the pupil possesses the general instruction required, and that he has made with success the technical studies prescribed; and to determine further that the pupil is fit to continue his studies.

"The knowledge required at this examination is—

"A. Special science.

"Exploitation, management, estimation of woods technology, protection of state forests, and forestal history and bibliography.

"B.—Auxiliary sciences.

"1. Mathematics: Elementary principles of statics and mathematics.

"2. Natural History: principles of the classification of animals, plants, and minerals. A. Zoology: divisions of the animal kingdom mammalia, birds, and insects, looked at from a forestal point of view; entomological nomenclature, structure and habits of insects in general, and special study of those which are useless or harmful to forests. B. Botany: classification, description, physiology, and structure of plants, and special knowledge of those which are useful from a forestal point of view. C. Mineralogy: general notions of geognosy and geology; general idea of the formation and the upheaval of mountains; influence of the subsoil on vegetation, and special study of the minerals and rocks useful to the forester. D. Physics and chemistry: general properties of bodies; notions in regard to light, heat, magnetism and electricity; carbonization, resin, and tannin.

"3. Legislation and jurisprudence: history of Prussian law: notions of civil and penal law as applied to forests.

"The examination takes place in general once a year, in September or October, before a commission appointed by the Minister of Agriculture, Domains, and Forests. This examination is held, one part in doors and another part in the forests; if it prove satisfactory, the forest pupil receives the title of *Forst-Candidat*.

"In case of failure he is allowed to re-commence his trials, in whole or in part.

"To continue his preparation, the forest-candidate should devote himself to personal studies in the forest, and, moreover, take an active part in all forestal works, in order that he may acquire under an *oberförster* all practical knowledge relating to forest economy, and forest administration. In the first instance, he is free to choose the circuit in which he wishes to prosecute his studies; but

the minister reserves the right to send him officially to any specified circuit.

"The *oberförster* near to whom the forest-candidate is sent is his immediate superior; and the candidate should take for his guidance in his service the instructions issued to forest overseers. The duration of the stage imposed on a forest-candidate is at least two years. He should pass eight successive months, which should always comprise the interval between December and April, in discharging the duties of a forest-guard in the same circuit, and in a particular part of the circuit. This part is chosen by the *oberförster* according to indications made by the inspector, and the candidate should give himself entirely to all the works of the guards, engaging in the surveillance, as well as in the exploitations, estimates, measurement of trees, sales, and the cultural operations going on.

"During these eight months he cannot be employed in the office of the *oberförster*.

"Then the candidate ought to visit different circuits: the design of these visits being to make him familiarly acquainted with all the kinds of trees growing in the forest, to give him explicit conceptions of different modes of exploitation and management; in fine, to give him practice in all kinds of forest business by making him take part in all the operations of an *oberförster*.

"During this stage, the candidate is required to keep a journal. This journal ought to indicate the circuits in which he has had a charge, their situation, their soil, and the exploitations and works of culture in which he has had to take part, &c.

"It ought, moreover, to contain notices of remarkable facts which have struck the candidate, and the observations which have been suggested to him by the study of the forest, and by the works which he has had to do in the office of the *oberförster*.

"The journal should be sent to the *oberförster* on the first of every month, and submitted to the superior agent present in the circuit, if such there be.

"In fine, when the candidate leaves the circuit, the *oberförster* should indicate the date of his departure, and give testimonials of his conduct; if there be occasion for observations in regard to faults of want of punctuality and obedience on the part of the candidate, or especially if he have shown a real incapacity for the work of the forest service, he is bound to make his report of it to the *Forst-Meister* inspector, and to the conservator.

"The Minister of Agriculture and Forests can exclude from the service every forest candidate who may have manifested notorious misconduct or negligence, or any candidate whose progress may be considered unsatisfactory.

"Every *oberförster* ought to send to the inspector, at latest on the 5th January in each year, a statement of the opinion of the candidates who have passed in the course of the preceding year more than four weeks in his circuit. The inspector adds to this his own observations. When the candidate has discharged the duties of an overseer, the inspector should give the result of the examination which he has made of the district entrusted to the management of the candidate; these documents are sent by him to the General Directory before the 15th January; they are collated and compared with those furnished by the conservator, and are then sent to the Minister to form the file of papers relating to the candidate.

"When the candidate has completed his course, done all the prescribed works, and satisfied the requirements of the military service, he may address to the minister an application to be allowed to pass the State examination: the time granted for this is five years from the passing of the last examination.

"To this application are attached the following papers:—1. A *curriculum vite*. 2. The diploma of study at a gymnasium. 3. The diploma of Forest pupil. 4. The certificate of diligence in the course of a school of forestry. 5. The journal. 6. Lastly, for candidates who belong neither to the corps of *feldjäger*, nor to the battalions of chasseurs, a document attesting that they have satisfied the military service.

"When there is nothing to hinder the authorization being given, the candidate is sent before a commission, who inscribe it, and fix for him the date of his examination.

"This examination is conducted according to the instructions and regulations of the minister, partly indoors and partly in the forests. The latter is by far the more important; it determines whether the candidate has acquired practice and knowledge of administrative questions.

"The examination turns on all parts of forest science and of forest economy in their connection, on the application of special law and common law to forest letters, and on the police and administration of the chase.

"The candidate having been subjected to this examination once, receives from the commission the title of '*candidat-oberförster*,' and is inscribed on the roll of officials going through their course of training.

"If the candidate do not pass the examination with success, the commission decides if he shall recommence his trials in whole or in part after a delay which cannot exceed six months.

The *candidat-oberförster* is employed in the royal administration so far as this is practicable until he receives his appointment, and he is bound to apply himself to the forest works which the minister may entrust to him.

"If the *candidat-oberförster* undertake the administration of communal forests, of public establishments, or even of private persons, he ought to communicate this to the minister; and this undertaking is not in any way a reason for excluding him from the Royal service; but it is clear that the years spent thus are not reckoned to him as years spent in service.

"And in case a candidate, after a certain lapse of time passed thus beyond the Royal service, should refuse a work which the administration would give to him, he may, on the proposition of the

minister, he removed from the roll of officials going through their course of training.

"Each *candidat-oberförster* is bound to make known, through the *oberförster*, his presence to the inspector, and to the conservator of the forest in which he finds himself, that whether he belongs to the Royal service, or that he be administering private forests. Likewise, on each change of residence he should make a similar communication to the same agents.

"In order to acquire a more extended instruction, and perfect himself in the general practice of business, aspirants to the forest services should, beyond their technical studies, go through a course of law and of political economy at a university. The candidate is free to make choice as to the time at which to pursue these studies, and that which may best suit him while prosecuting his preparation. But it is preferable that he should take them up while he is a *candidat-oberförster*.

"The *candidats-oberförster* who, besides the ordinary prescribed forest studies, give themselves for at least two half-year sessions to the study of these political sciences, can, after having been attached for one year to a directory of finance, address to the minister an application for permission to submit to an examination on the matters spoken of; which application should be accompanied by a certificate of his having followed a course at a university. This examination is conducted before the superior commission of forests, by the Minister-adjunct to the special examiners for legislation and political sciences. It turns on the application of civil law in Prussia to the administration of forests, and principally on the administration of law and political economy.

"The trials ought to show if the candidate possess the knowledge necessary to enable him to discharge in a satisfactory manner the functions of a member of a forest directory. The *candidats-oberförster* who pass this trial successfully receive from the minister the title of *forst-assessor*. The inspectors of *forst-meisters* are chosen from among the *oberförster* who have most distinguished themselves in their service, and preferentially from amongst those who have passed the last mentioned examination.

A translation of these extracts appears in the *Revue des Eaux et Forêts* for last month, which indicates somewhat the importance which is attached to them.

JOHN C. BROWN.

—*Journal of Forestry.*]

SERICULTURE.

THE prime reason, says the *American Entomologist*, why the mulberry silkworm must ever be the silk producer of commerce, aside from the superior quality and quantity of its silk, is, that it is a domesticated insect, and that the worm can be fed in large quantities in partial confinement and under control; further, that while enduring the artificial life it shows no disposition to escape from the shallow trays upon which it is fed. All the other worms suffer more or less when brought together in large numbers, or when confined or sheltered, and in this fact, more than in any difficulty in using the silk, lies the secret of the failure to substitute any of them for *mori*.

SILK INDUSTRY IN KASHMIR.

SERICULTURE is not a new speculation among the Cashmirees. It is known to them from very early period. It is said, that a Chinese princess first introduced the silk in Cashmere by secretly putting some eggs of *Bombyx Mori* under her hair lock when she was leaving her father's roof for her husband in Cashmere, as then there was a great restriction and heavy penalty for taking out the silk eggs off the walls of China, and thus she introduced it in Cashmere, her husband's kingdom. Since then it has been a very favorite industry among the Cashmirees who were rearing and spinning the silk in a juvenile rude system which is generally known under the name of "home spun." Filature was not known to them until Baboo Nilamvar Mukherjee, the renovator of the silk industry in Cashmere, introduced the system of high culture and machine reel, and succeeded in harvesting the crop of cocoons yielding silk and floss of value not less the £15,000 annually. But in the course of few years it showed its tendency to fall, and by and by it suffered so heavily, that a grain of eggs was not left. This sad failure was due to some unexpected natural phenomena to which the truth of Cashmere famine lies. A plague spread

among man and beast, the worms were not excepted, and thus ended the golden era of the silk industry in Cashmere.

His Highness the Maharaja not liking to allow this fine industry to disappear from his territory, caused the silk worms of France, Italy, Bokhara and Japan to be acclimatized, and accordingly M. Ermens, the Superintendent of his vinery and distillery, was instructed to import some eggs of silk worms from France and Italy. The consignment reached us in the April of 1880, but they all proved a total failure. The next year Mr. Henvey, then the officer on special duty, Srinuggur, kindly undertook to import some eggs from Japan. The eggs reached Srinuggur in cards very sound and healthy, and yielded a crop of cocoons in the proportion of $\frac{1}{2}$ oz. of eggs to 2 lbs. of cocoons all the cocoons thus obtained were bred, and eggs were kept for the next season.

This is the origin of the second era of our Cashmere sericulture. From this little beginning we now expect to harvest a considerable crop of cocoons, aggregating the value of £9,000 in round numbers, and by this change of eggs we have succeeded in renewing and imparting a healthy and fresh impulse to our long-cherished industry of Cashmere.

S.

Jummoo, May 20, 1883.

NOTE.—The above note on silk is written by a native gentleman, whose English we have deemed it best to leave untouched.—Ed., J. A.

TEA.

THE TEA TRADE AND EASTERN BANKS.

IT is, we learn, widely feared in the city of London that Eastern Banks have sustained irrecoverable losses by the tea trade of China. That trade is being ruined by the rival that it finds in India, yet each season finds the British, Australian, American, German, and Russian merchants at the treaty ports as intent as ever on competing against one another, and still prepared to pay "that heathen Chinese" prices far beyond the range of quotations current in Europe. The Chinese have a faculty for combining against the foreigners, and as they have not yet experienced difficulty in obtaining old prices for the tea that they bring to market, they do not allow their minds to be exercised by the more or less vague stories about Indian tea that reach them. Their customers at the ports are none too ready to credit all that they are told, or read, about the tea trade of India. They cannot yet bring their minds to believe that the day may not be distant when India will be the death of the tea trade of China. They hope on, season after season, that there will be a change for the better in the home market, and that a bumper year will more than compensate them for the heavy losses of several years. They remember that years of scanty profits have in former days been followed by years of grand returns; and they cheer themselves with the belief that the history of the tea market will repeat itself. And probably it would do so if China continued to possess the monopoly of the world's tea trade. Unfortunately for her tea growers and tea merchants, but fortunately for the world, she does not now retain more than about two-thirds of the world's custom. India has, in a dozen years, carried off the other third, and year by year will she obtain a larger slice of the trade. It may be that at the eleventh hour the tea shippers in China will be constrained to offer a united and irresistible opposition to high prices and low qualities, and thus succeed in competing on somewhat equal terms with India. But as yet prices rule obstinately high in China, and qualities get worse and worse. Indeed, were it not for the ready ability of Indian tea to blend with and raise the character of China tea, much of the latter would go out of consumption of Europe, the United States, and Australia. The Indian teas are now very largely, yet still unconsciously, consumed by the tea-drinking world. The ordinary house-keeper has no idea that tea is grown anywhere else than in China, and the Indian product does "good by stealth," by importing a much needed flavour to the abundant shipments of China tea of low quality. But the palate of the tea-drinker is being educated to like the characteristic taste of Indian tea, and dealers find it increasingly difficult to palm off tasteless China stuff. In short, the "one-eyed barbarian" of the far West is acquiring a capricious palate, and the Chinese must either contrive to sell good and relatively cheap tea, or retire from competition with India and the Indians.

Meanwhile, the tea trade of China is falling more and more into the hands of men of straw supported by local banks. The old firm whose

names are names to conjure with in Mincing-lane, have, to a great extent, drawn aloof from any other than a safe commission trade, and left the field to plungers and speculators, who are believed to be, in very many cases, inextricably in the books of Banks on the wrong side of the account. The latter continue to draw up to the hilt against bills of lading, and the banks, to keep them going, negotiate their drafts hoping that sooner or later the market will recover, and that losses may be recouped. And the Chinese themselves lend a helping hand to shaky firms, which assist in keeping up prices at the opening of the tea season. Thus it happens that last season's China teas are selling in England and Russia at wretched prices, showing a loss of 5*l.* to 6*l.* per lb. on their cost in China. A London correspondent of the *Times* considers that:—

"The one remedy for the present condition of things is that the great bulk of the so-called fine teas should be bought in China at their present value on this market—viz., at about 5*l.* to 6*l.* below the prices given for them in recent years. With the large accumulated stocks in Russia and consequently reduced orders from that country, the yearly-increasing supply of Indian tea, and the present prices here, one would think that such a course would at once be adopted. Unfortunately, however, so much of the tea is bought on commission, and the Russian agents seem so reckless as to the prices which they give, that any such prudent action can hardly be hoped for. It would, therefore, be wise for holders of shares in Eastern banks as well as all who have been in the habit of intrusting orders to buying agents in China to ponder the foregoing facts, which can be easily verified by a reference to any of the trade circulars, lest their money should be lost in the crash which must certainly take place if the past policy of tea buyers in China be continued."

It seems probable that India will obtain with her tea a potential compensation for her loss of revenue from opium. Major Baring takes a desponding view of opium, and believes that the trade will show yearly a tendency to fall off. India's loss in this direction will be China's gain, for it will be attributable to the increased cultivation of the poppy in China. Similarly in regard to tea, China's loss is India's gain. But we do not like the prospect of having some day to seriously consider how to make good the loss of the seven millions sterling that India now realises from opium.

The value of the tea exported from India in 1881 was less than half this sum. Obviously, however, our tea is doing India a good turn, and promises to do yet more for the land to whose soil it takes so kindly.—*Madras Mail.*

INDIAN TEA.

THE grievances which the Indian tea planters have laid before the Secretary of State are not wholly groundless, though the remedy should probably be sought in another direction. The most formidable matter of complaint is that Indian teas are "bulked" by her Majesty's customs—that is say, each chest is opened and emptied, in order to ascertain the exact weight of the tea and of the package. The planters say, truly, that this process greatly injures the quality of the tea, by exposing it to the humid atmosphere of London, and it destroys the air-tight lead lining of the chests, which never can be, or, at all events, never is perfectly reinstated. What the planters claim is that one or two chests only out of a "break" shall be opened, and the tare so found apply to the whole. The answer which the petitioners are likely to receive to their prayer is that the customs are not to blame for the bulking of Indian tea but the trade, who will not buy the tea unless it is bulked, for the perfectly sufficiently reason that the weight and tare of the packages, as well as the quality of the tea, are so irregular, that no average can be taken. Undoubtedly the bulking of Indian tea inflicts a serious burden on the trade, not only through the expense, but the destruction of the chests and their contents. The time, moreover, required to prepare the tea for sampling keeps it for a week or ten days out of the market after arrival. The remedy for this state of things appears to be to take another leaf out of that great Chinese book from which Indian planters have already taken so many. Chinese tea comes to market so perfectly packed, that in a break of 600 chests you will find an absolute uniformity of weight, both of package and contents and of quality, so that no repacking is needed, and the whole can be sampled and sold the moment the steamer breaks bulk. The reason is that the Chinese carry on their tea business on true commercial principles, while the Indian planters are still in the wasteful stages of a half-developed industry, and have not yet learned the full advantage of the division of labour. The planter is, or tries to be, merchant, carpenter, and engineer, as well, and one meets with persons holding shares in tea estates who harbour the delusion that they can not only send their tea to Calcutta for sale, but ship it to London, and, passing over the machinery of Mincing-lane, follow their pounds of tea into the consumers' pot. With such crude ideas of commerce, it is perhaps hardly to be wondered at that the Indian tea trade finds itself under some disadvantage.

The number of gardens in India is, according to the planters, 2,700 or 2,800, scattered over a wide area, and in very varied situations, and it would be absurd to look for uniformity or even reasonable similarity either in the product or the packages. The gardens are individually very small: yet every garden possesses a more or less elaborate plant, consisting of firing houses, rolling-machines, &c., and each has to keep up a staff of handicraftsmen to manage the machinery and to make the tea chests. The enterprise is thus severely handicapped at the outset, much as a small farmer would be who kept his own steam plough and reaping machine. The men and machines are necessarily half their time idle. The only true remedy for this is to organise a market on the Chinese method for the green leaves in the districts. Darjeeling is admirably situated for such a market, and there are several stations in Assam

which would make most convenient depots for the purchase of tea. What is wanted is sufficiently strong companies or private capitalists to establish themselves at these centres, and set up all the necessary machinery for manufacturing and packing the leaf. The planters would then, like the Chinese, sell their basketful of leaves as they plucked them from the bushes. They would be planters, and nothing more, and the better planters for being nothing more. The tea-buyer, filling the functions of the *hong* in China, would collect the leaves in large storehouses, sort them out according to quality and kind, and manufacture the tea on a large scale with the *maximum* of skill and *minimum* of cost. The *hong* would pack the tea in large breaks of uniform quality, in chests of uniform size and weight, and such teas would never require to be bulked again, either in London docks or anywhere else.

The advantages to the planter of such an organization as this would be manifold. In the first place, he would be relieved of the great load of financial anxiety which he bears at present. He starts the season under a mass of debt to the Calcutta agents, which has gradually to be worked off during the producing season. These advances cost very dear, and the repayment cannot be made till the tea has been gathered, manufactured, packed, and sent down by slow transport to the Calcutta market. Whereas, on the *hong* system, the planter would require very little advance at all, seeing he would need no machinery nor any expensive staff to work it, and he would receive his money as fast as he gathered his tea, instead of waiting two or three months for it, as at present. The chief difficulty in the way of this innovation would be the strenuous opposition of the Calcutta agents, who make good revenue out of the tea-planters, not only in the way of interest on advances, but commission on sales of tea and on supply of stores and machinery. For once a tea concern is under the protection of a Calcutta house, it is an understood thing that it is nearly impossible to escape therefrom. The emancipation of the tea planters from this thralldom would fill them with new energy, and probably enlarge their intelligence.

Calcutta is at present the mart for Indian tea, mainly because under the present regime the tea has to pay toll to the finance houses there. Calcutta will always be the great shipping port for tea, nor is there any reason why it should not continue to be a market also; for the tea-buying establishment which I have been supposing at Darjeeling, Gowhaty, &c., would have quite enough to do to bring the tea down to Calcutta in a state fit for the London market, without following it any further. There will always be plenty of buyers for the London market in Calcutta.—*Correspondent of the Times.*

THE GREAT REMEDY FOR PRICKLY HEAT, INDIGESTION, HEADACHE, BILIOUSNESS, AND FEVERS.

The testimony of medical gentlemen has been unqualified in praise of

LAMPLOUGH'S PYRETIC SALINE,

As possessing elements most essential for the restoration and maintenance of health with perfect vigour of body and mind.

It is Effervescent and Tasteless; forming a most Invigorating, Vitalising, and Refreshing Beverage.

Gives instant relief in HEADACHE, NEURASTHENIA, BILIOUSNESS, CONSTIPATION, INDIGESTION, LAMPS, DE, HEARTBURN, and FEVERISH COLDS; prevents and quickly cures the worst forms of TYPHUS, SCARLET, JUNGLE, and other FEVERS, SMALLPOX, MEASLES, and ERIPTIVE or SKIN COMPLAINTS, and various other altered conditions of the blood.

Dr. FROST:—"Unfolding source of immense benefit to mankind."

Dr. MORGAN:—"It furnishes the blood with its lost saline constituents."

GOVERNMENT OFFICIALS AND PLANTERS caring for the welfare of their employes should note its value as a specific in Fever cases.

Dr. J. W. DOWLING:—"I used it in the treatment of forty-two cases of Yellow Fever, and am happy to state I never lost a single case."

Dr. W. STEVENS:—"Since its introduction the Fatal West India Fevers are deprived of their terrors."

H. E. MAJESTY'S REPRESENTATIVE the GOVERNOR OF SIERRA LEONE in a letter of request for an additional supply of the Pyretic Saline states:—"It is of great value, and I shall rejoice to hear it is in the houses of all Europeans visiting the tropics."

Dr. SPARKS (Government Medical Inspector of Emigrants from the Port of London) writes:—"I have great pleasure in bearing my cordial testimony to its efficacy."

Dr. TURLEY:—"I found it act as a specific, in my experience and family, in the worst forms of Scarlet Fever, no other medicine being required."

Dr. E. GIBBON (formerly Physician to the London Hospital):—"Its usefulness in the treatment of disease has long been confirmed by medical experience."

Dr. W. F. PINDER, PUNJAB, INDIA:—"We firmly believe that the use of your Pyretic Saline will do more to prevent fever than all the Quinine ever imported can cure."

Dr. E. GIBBON (formerly Physician to the London Hospital):—"Its usefulness in the treatment of disease has long been confirmed by medical experience."

To be obtained of any Chemist or Drug Store, in Patent Glass-stoppered Bottles, 2s. 6d., 4s. 6d., 11s., and 21s. each. Please note in connection with the recently observed effects of the use of Citrate and other preparations of Magnesia that LAMPLOUGH'S PYRETIC SALINE is warranted not to contain any substance which would cause calculous or other earthy deposits.

H. LAMPLOUGH, 113, HOLBORN HILL, LONDON, E.C.

ZULULAND AND CETEWAYO.

"I know what it is," he answered; "this honey is made from euphorbia flowers, which are very poisonous." This explanation made me feel exceedingly uncomfortable; but I elicited from him that there was not much danger, as the 'maass' taken with it would neutralise the effect of the poison. Directly he mentioned poison I dived into the packs, and pulled out a bottle of ENO'S FRUIT SALT, and emptying a quantity into two pannikins, filled them up with water, and several times repeating the dose, in a few hours we were considerably better."—*"Zululand and Cetewayo," (p. 139), by Captain W. R. Ludlow, 1st Batt. R. F. Royal Warwickshire Regiment.*

"What on earth shall I take to Zululand?" asked my friend Jim Law one day at Aldershot, when he had just received orders for South Africa, to start at forty-eight hours' notice. I replied, 'If you take my advice—and it's that of an old traveller—you'll not budge without a few bottles of ENO, even if you leave half your kit behind. I never am without these Salts, and, please the pigs, never intend to be.' On his return I inquired, 'Well, how about ENO'S FRUIT SALT?' 'My dear fellow, it was the best advice you ever gave; they saved me many an illness; and when I left Tugela, I sold the remaining bottles for ten times the original price!'"—*Lieut. Col.*

JEOPARDY OF LIFE. THE GREAT DANGER OF DELAY.

You can change the trickling stream, but not the raging torrent.

WHAT EVERYBODY SHOULD READ.—How important it is to every individual to have at hand some simple, effective, and palatable remedy, such as ENO'S FRUIT SALT, to check disease at the outset! For this is the time. With very little trouble you can change the course of the trickling mountain stream, but not the rolling river. It will defy all your tiny efforts. I feel I cannot sufficiently impress this important information upon all Householders, or Ship Captains, or Europeans generally, who are visiting or residing in any hot or foreign climate. Whenever a change is contemplated, likely to disturb the condition of health, let ENO'S FRUIT SALT be your companion; for, under any circumstances, its use is beneficial and never can do harm. When you feel out of sorts, yet unable to say why, frequently without any warning you are suddenly seized with lassitude, disinclination for bodily or mental exertion, loss of appetite, sickness, pain in the forehead, dull aching of back and limbs, coldness of the surface, and often shivering, &c., &c.; then your whole body is out of order, the spirit of danger has been kindled, but you do not know where it may end: it is a real necessity to have a simple remedy at hand that will answer the very best end, with a positive assurance of doing good in every case and in no case any harm. The pilot can so steer and direct as to bring the ship into safety, but he cannot quell the raging storm. The common idea when not feeling well is, "I will wait and see, perhaps I shall be better to-morrow;" whereas, had a supply of ENO'S FRUIT SALT been at hand, and use made of it at the outset, all calamitous results might have been avoided. What dashes to the earth so many hopes, breaks so many sweet alliances, blasts so many auspicious enterprises, as untimely death?

ENO'S FRUIT SALT.—"After suffering for nearly two and a half years from severe headache and disordered stomach, and after trying almost everything and spending much money without finding any benefit, I was recommended by a friend to try ENO'S FRUIT SALT, and before I had finished one bottle I found it doing me a great deal of good, and now I am restored to my usual health; and others I know that have tried it have not enjoyed such good health for years.—Yours most truly, ROBT. HUMPHREYS, Post Office, Barrasford."

SUCCESS IN LIFE.—"A new invention is brought before the public, and commands success. A score of abominable imitations are immediately introduced by the unscrupulous who, in copying the original closely enough to deceive the public, and yet not so exactly as to infringe upon legal rights, exercise an ingenuity that, employed in an original channel, could not fail to secure reputation and profit."—*ADAMS.*

CAUTION.—Legal rights are protected in every civilized country. Examine each Bottle, and see the capsule is marked "ENO'S FRUIT SALT." Without it you have been imposed on by worthless imitations. Sold by all Chemists, price 2s. 9d. and 4s. 6d.

DIRECTIONS IN SIXTEEN LANGUAGES HOW TO PREVENT DISEASE.

Prepared only at ENO'S FRUIT SALT WORKS, HATCHAM, LONDON, S.E., by J. C. ENO'S Patent.

SUTTON'S SEEDS.

TESTIMONIAL.

From S. Jennings, Esq., late Vice-President of the Agri-Horti. Society of India.

"With reference to your mode of packing seeds for export, I must say how much I was gratified with the system you were so good as to show me. During the whole of my long Indian experience, it was my constant regret that English packed seeds were almost invariably lower in germinating power than the American. After seeing the elaborate precautions you take in executing such order as that of the Agri-Horti Society of India, I am by no means surprised to hear that you have been gratified by the receipt of so much testimony from the tropics as to the condition of your seeds upon arrival."

Berlin, 1879.

Melbourne, 1880.

1878.

Cincinnati, June, 1880.

OVER 450,000 FEET SOLD DURING 1881.

Including 3,877 feet of main Driving Belts, of widths ranging from 13 in. to 60 in., are working in over 6,000 Mills and Works in Europe and America.

The following Tests (by Kirkaldy, of London) show the relative strength and value, compared with Leather.

| | Breaking Strain per Square inch of Section. | Price per foot. |
|-----------------------------------|---|-----------------|
| Best Double Leather 6 in. Belting | 3,572 lbs. | 5s. 7d. |
| Gandy's 6 in. x 8-ply Cotton | 6,811 lbs. | 2s. 6d. |

THE GANDY BELT.

Any Length or Width
for Main Driving.

It is the best belt ever made for all purposes. Much Cheaper and Stronger than Leather. Thoroughly Waterproof, and not affected by temperature, clings well to the pulleys, runs true, and can be made any length without joints.

This Series of Belting (see engraving) was supplied in One Order to Messrs. John Crossley and Sons, Halifax, May 1, 1880, and continues to give entire satisfaction.

THE "GANDY" BELT.

GANDY'S Patent American Cotton Belting can claim a superiority over leather belts in every particular; its cost being about half that of leather, while its strength and gripping power is about double that of the best leather, as shown by repeated tests taken by Kirkaldy, of London. These tests are given above, to which special attention is directed. These "Gandy" belts are made of any width up to 72 inches, and any length up to 340 feet without joint, thus obviating the necessity of having two belts on the same pulley, a system of driving which is never satisfactory, as it is impossible to have belts of exactly the same tension; hence one or the other is always causing a stoppage. These stoppages are avoided by using Gandy's Patent Belts in one width. These Gandy Belts are made of the finest American Cotton Duck, specially prepared at Baltimore for the purpose, and then put together and finished by Gandy's patented special Machinery and process to prevent stretching, and render them impervious to atmospheric influence. Possessed of advantages such as these, the universal adoption of Gandy's Belts can only be a question of time.

A SUBSTANTIAL GUARANTEE GIVEN WITH EVERY MAIN DRIVING BELT.

FIRE BRICKS.

RANEENGUNGE FIRE BRICKS as supplied to Government and the various Railways, Iron Works, Coal, Gas, and Steam Navigation Companies. Price—Rs. 9 per 100.

Extract from Official Report of tests made at H. M.'s Mint, Calcutta, by THEODORE W. H. HUGHES, Esq., F.C.S., A.B.S.M., Officiating Deputy Superintendent, Geological Survey, India:—

"The Fire Bricks tested by me were furnished by the Firm of Messrs. BURN & Co. * * * The materials from which they are made are very refractory and capable of resisting high temperature without sensibly fusing. * * * That compared with Stourbridge Fire Bricks are somewhat superior."

The specimens were subjected to a temperature of over 3,000 degs. Fahr., the smelting point of Cast-iron being 2,786 degs. Fahr.

Apply for the above, and for Raneengunge Salt-glazed Stoneware and Imperishable Drainage Pipes, to

BURN & CO.,

7, Hastings-street, Calcutta,

or Raneengunge Pottery Works, Raneengunge,

E.I.R., Bengal.

We publish the following papers at this Office:—

THE INDIAN AGRICULTURIST.
(MONTHLY.)

Rates of Subscription, including postage.

STRICTLY IN ADVANCE.

HEALTH, STRENGTH, AND ENERGY.

DR. LALOR'S PHOSPHODYNE.

(Trade Mark—Phosphodyne.)

TWENTY YEARS' PUBLIC TEST, AND THOUSANDS OF TESTIMONIALS FROM

ALL PARTS OF THE WORLD ESTABLISH

PHOSPHODYNE

as the only Safe, Reliable, and Never-failing Phosphoric Remedy for Over-worked Brain, Sleeplessness, Harassing Dreams, Worry, Anxiety, Excitement, Epilepsy, Business Pressure, Wasting Diseases, Nervous Prostration, Stomach and Liver Complaints, Impoverished Blood, Premature Decay, and all morbid conditions of the system dependent upon the deficiency of the Vital Forces.

DR. LALOR'S PHOSPHODYNE PURIFIES AND

Enriches the Blood, Clears the Skin, thoroughly Invigorates the Brain, Nerves and Muscles, Re-energises the Failing Functions of Life by supplying the Phosphoric element which has been wasted, and thus imparts Energy and Fresh Vitality to the Exhausted Nervo-Electric Force, and rapidly Cures every form of Nervous Debility, Paralysis, Kidney, Nervous, Mind, and Heart Diseases, from whatever cause.

This elegant Phosphatic combination, the Wonder of Modern Chemistry, is pronounced by the most eminent members of the Medical Profession to be unequalled for its power in replenishing and elaborating the Vitality of the Body; by its supplying all the essential and vitalising constituents of the BLOOD, BRAIN, and NERVE SUBSTANCE; and for developing all the Powers and Functions of the System to the highest degree; by its being agreeable to the palate, and innocent in its action. While retaining its wonderful properties, it acts as a Specific, surpassing all the known THERAPEUTIC AGENTS of the PRESENT AGE, for the SPEEDY and PERMANENT CURE of the above diseases.

DR. LALOR'S PHOSPHODYNE is sold in Bottles at 4s. 0d. and 11s. by all Export, Wholesale, and Retail Medicine Vendors throughout the World.

IMPORTANT NOTICE.—NONE IS GENUINE UNLESS the name, Dr. Lalor's Phosphodyne, London, England, is blown in the Glass of each Bottle, and every Bottle bears the British Government Stamp, with the words DR. LALOR'S PHOSPHODYNE, London, England, engraved thereon by Order of her Majesty's Honourable Commissioners; if not, it is a FORGERY, AND YOU HAVE BEEN IMPOSED UPON BY A WORTHLESS IMITATION.

MANUFACTURED ONLY AT THE

PHOSPHODYNE LABORATORY BY

DR. ROBERT D. LALOR,

BAY HOUSE, 32, GAISFORD-STREET, LONDON, N. W.

(THE SOLE PROPRIETOR AND ORIGINATOR OF PHOSPHODYNE.)

THE AGRA BANK,

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigha in particular varies so much in the different provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

The Indian Agriculturist.

CALCUTTA, JULY 2, 1883.

AGRICULTURAL MAXIMS.

IT does at first appear astonishing that Hindoos, essentially an agricultural people, should be so ill-provided, if at all, with works on agriculture ; but the surprise is to a great extent removed, when we reflect that the great mass of Indian agriculturists are illiterate, and are well provided with instructive maxims and tales which may be supposed to supply the place of books very fairly, with the superior advantage of being suited to the capacity of the people. These proverbs, generally in rhyme to render them easy of recollection, are obviously of great antiquity, and, having stood the test of generations of practical agriculturists, may reasonably be supposed to be of considerable value.

What we wish to suggest is that these rhythmical proverbs, as well as set phrases and tales, should be collected by some means from all parts of India, and after revision with the object of expunging indecent expressions which, with a little ingenuity, may readily be replaced by more parliamentary ones, a book should be compiled from the information contained in them, due allowance being made for the mythical and marvellous which pervade all Indian literature, and, as in the case of Indian history, must be collated before tangible conclusions can be arrived at. Agriculture, however, is such a practical subject that a condition involving an entire dependence on marvellous fables could never exist, and this difficulty will no doubt be easily overcome. The thoroughly practical tenor of the following proverbs, which I give in the Birj Bhesha (the language of the sacred circuit of Muttra the purest Hindi spoken, I believe), will show that cultivators themselves recognise the absurdity of depending on mysterious omens alone :—

Ghar me saru swarehi, aur tina ke sikh Sacan gai haraito tina mango bhik.—

which, translated, means :—You will go begging should you do either of the following three things,—1st, sit at home idling with your able-bodied relatives (brother-in law in the rhyme) ; 2nd, take the advice of women, and 3rd (which is to our purpose), go searching for omens as to the proper time to sow your seed

after the month of Savan (between 12th July and 19th August 1888) has passed.

Karam hoi jai khot na tole—

Which really means, Let fortune desert me, provided I retain my manure.

Ban qat ban karé to bhag mālām paré—

Sow cotton in a field that had cotton in it (the previous season), and you put your good luck to (a severe) test.

These proverbs clearly advise not to depend on omens and luck, but to work hard, following well-known and substantial practices.

Setting aside the value of it to uninformed people desirous of following agriculture in India, the book would surely be of the greatest use to officers of the Agricultural Department. It would facilitate their endeavours to introduce improvements, as it would give in a very accurate form the opinions and practices of the mass of the people in various parts of the country, obviating in a measure the possibility of erroneous impressions being formed, and perhaps very often save the expense of experiments: as these ancient proverbs can only be looked upon as conclusions, the results of experiments of the highest order. It would also shew scientific men clearly what is known, and what remains to be known by natives.

Dictionary form is perhaps the very worst for conveying information of this sort, and it would probably be best to combine in the same book with a list of the maxims, which should be numbered, a treatise based solely on information contained in them.

For instance, the following proverbs, numbered from 1 to 5, have reference chiefly to cotton:—

(1.) *San ghano—Ban bēro—mālki phandī Juar pēra pēra par Bājra-gaudaro se hōr.*

Hemp should be sown closely. Cotton scattered. Juar about the jump of a small frog (a span) apart, and should bajra be sown a pace (5 feet) apart, the cobs will be as long as the axle of a well wheel.

(2.) *Ban mē bēn tara to bhag mālām paré.*

Sow cotton after cotton, and we will ascertain the quality of your luck.

(3.) *Do puttī cheon na narie aur bīnat cheon pastē.*

You did not weed your cotton when it shewed but two leaves; now why do you repent while picking?

(4.) *Jo bursiagi Suānt renthā chālē na tānti.*

Should it rain in the zodiacal sub-sign of Suānt (between 22nd October and 5th November) neither the cotton gin or cotton beater's bow will work.

(5.) *Jonhri kuhāt kiān se hai ki beg naraē, nahni nahni gār dē, aur bhutta validilā dē, to rot tu khwaān. Ban kē hoi tē tent, bhaj wa me tē dīwān. Līl kabras? Līl kajhuto jhoyro aur kahē Girdhar kabras chānd par bōjo jāto.*

Jonhri says to the cultivator—Sow and weed me well, ploughing over me with close furrows (when a few feet high) and I will give you ears that will bend with their weight and feed you with bread. Sow cotton and I will pay your rent with the produce of the pods, but as for indigo, oh, poet! it is a mistaken business, and says Girdhar the poet, shoe-blows will resound on your head (for your folly) in writing about this product.

These could be put in the following form, giving the numbers of the proverbs—

(No. 1) Cotton should never be sown closely but as far apart as possible, (No. 3), and should be weeded while very young and before the plants have thrown out more than two proper leaves: without this early weeding, the produce is certain to be very indifferent. (No. 2) Sowing cotton in a field that has had cotton in it the preceding season, is found by experience to be very bad; and under ordinary conditions no hope of a good crop can be entertained where this is done. (No. 4) Rain in the days contained in the zodiacal sub-sign of suānt (between 22nd October and 5th November) is ruinous to cotton and reduces the harvest to a mere nothing. (No. 5) Cultivators depend greatly on cotton as a means of paying their rents, and make it a principle of looking upon it as a crop set apart specially with this object.

Of course, with more maxims, &c., to refer to, reasons could be given and pages of valuable instruction written.

Perhaps it would be necessary in preparing the book to devote a few pages to astronomical matters, such as the 12 signs of the zodiac further divided into 27 parts, called Naichattras, the names of which are continually in the mouths of cultivators and others interested in agriculture, as all occupations with regard to time of sowing, ploughing, &c., are regulated by these periods. Each zodiacal sign contains 2½ of these sub-signs or Naichattras, meaning 9 canopies, I presume, there being 9 in each 3rd section of the year. The following table compiled from the Hindi almanac, published monthly at Agra, will show the English dates for the present year on which the sun passes through these signs. The hours and minutes have been omitted:—

| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |

| | | 12th | | 16th | | | | | | |
| Hindi months | | | Phagun. | 11 days of Chait Samat 1041. | | | | | | |

The following proverbs will show how their Naichattras are spoken of:—

Ohana Chitra Changua santhan gehun hoi.

Grain sown in Chittur (14) will be four times more fruitful (than if sown at any other time), but wheat grows best when sown in Suanth (15).

Pak Punarbas baigē dhan Astekha kodon parman Magha masino baigē phar aur in hārān har dijio jhēr.

During Pak (3) and Punarbas (7) sow rice, in Astekha (9) at the very last sow kodon, after this in Magha (10) sow masina (or masina and mot vetches) ploughing these fields well.

Jo barēga Utrā nāj na khawē kūttrā.

Should it rain in Utrā phalēgunā (12) the very dogs will turn up their noses at bread (grain.)

Mirgair na bāt na bādian, Rohān natapē na Jet.

Adra Jo barē naktā to samē ki nēt.

No heat in Rohān (4) or in the month of Jet, no high winds in Mirgair (5), and if added to this there should be no rain in Adra (6), the season is ruined.

Jai dīn Jēt chālē Purwat, tai dīn Sivan sūkho jai.

For every day you have an East wind in the month of Jet, you will have a dry day in the month of Sivan.

Though these proverbs having reference to the *naichattras* may not be quite correct, they must be somewhere very near the truth to influence, as they do, thousands of practical agriculturists.

It may be mentioned that it is by no means an easy matter to collect these proverbs; people cannot readily recall them to memory when called upon to do so, and further, a man may be an excellent practical agriculturist without knowing more than a very few, though this does not appear to throw any doubt on the opinion expressed here that these proverbs, to the illiterate cultivator, really answer the purpose of a treatise on agriculture, for we know, judging from analogy, that one may be an excellent practical man without having read and studied any books treating of his profession. It would of course be far easier to get information from cultivators in the ordinary way, but Europeans have, and with justice, such an indifferent reputation for being able to procure correct information from natives, chiefly on account of the great disregard for truth displayed by the latter, and no doubt in some measure because of their not mixing with them, that bare assertions will always be received with doubt. How often do we find carefully written notes on agricultural subjects, rendered useless by the writer being obliged to acknowledge his own doubts as to the accuracy of statements he has made, because of the tendency manifested by his native informants to suppress the truth?

The support of ancient adages or maxims would, no doubt, be generally regarded as ample testimony of the correctness of statements made regarding Indian agricultural matters, and prove very interesting to readers, particularly those in search of information wanted for practical purposes.

There are generally a few old cultivators in each village or clump of villages with the reputed talent for remembering proverbs, &c., and collectors could procure a great number from them. It would also be advisable and facilitate matters to record reputed facts, and then search for maxims supporting them. For example, cultivators tell one that rain immediately after weeding injures and blights a crop, particularly cotton, and that a few days' dry weather intervening is beneficial. The knowledge of this palpably renders the scheme of securing a maxim supporting it much stronger.

W. C.

ON THE IMPOVERISHMENT OF THE BERAR SOIL: WITH SUGGESTIONS FOR ITS REMEDY.*

THE Indian cultivator has a very good idea of the value of manure in increasing the amount to be got from his land, in the shape of a crop; but his ignorance of the value of available manures, and the inherent productiveness of the soil, hinder the practical application of this knowledge. The manures which he believes in are cowdung and ashes, but these, owing to certain economic considerations, such as cowdung being used as fuel, can only be applied by him in limited

amount. The garden and irrigated land solely get the benefit of it, none being available for the ordinary fields. The mutual relation between animals and plants is disturbed, and the rule which makes it necessary that the waste products of animals should be returned to the soil for the use of the vegetables is continually violated. Owing to the shorter life of plants, cultivated for the food of animals, either directly or indirectly, any such breaking of this law is more quickly manifested by them than by animals: but sooner or later these latter suffer also. The stunted forms of the Gonds and Koorkoos are good examples of how a whole race may be reduced in size by insufficient food, and what has happened to them in their less productive soil, will overtake the inhabitant of the plains who is reducing his land to the same powerless state by withholding from it its natural food—manure. The carbonic acid, dung, and urine must be placed near the plant for its use, but instead of doing this, the cultivator takes no care that they can be so utilised, and the result is that year by year plants find less food in the soil, and become smaller and smaller each successive crop, until they cannot be grown with profit at all. When this happens land has to be thrown fallow, and a certain portion of the food-producing surface of the earth is lying idle and inactive.

The question is, what are the best means at our disposal for averting this result?

Before going to the question of manure, we may consider one means by which this state of exhaustion may be delayed. If grass seeds were sown at some regular interval of time on these plots, the land would obtain a rest, and it has been ascertained by Baron Liebig, that by growing grass on the land, not only is it not exhausted or merely rested, but the grass contributes to the nitrogenous supply of the soil, storing up ammonia in it for future use. I think that one great step would be taken if one of the numerous Indian grasses were selected, as rye-grass has been at home, and grown as a crop in a certain rotation. The production of this grass crop leads to a consideration of an easy method of extending the manurial resources of India. It is customary for a ryot who wishes to manure his field, to induce a shepherd to bring his flocks at night and herd them on it. The soil gets the benefit of the droppings and the urine. This herding is done for three or four nights, and the shepherd is paid for it. If the cultivator sowed some grass seeds on his land he could turn the matter to his own profit by getting the shepherd to pay for the grazing, and get the benefit of the manure as well. By adopting this course, some practical measures might be evolved which would be of use; but of course the subject needs to be thought over and worked out, as no one could at once produce a system of rotation of crops which would be applicable to a whole province, or even for many contiguous portions of it, as the soil varies so suddenly and so much. The rotation of crops is so intimately connected with non-exhaustion and husbanding the resources of the soil, that manuring and it must always be considered together, when any practical scheme for the non-impoveryment of the land is being drawn up. As farmyard manure practically does not exist in India, this plan of eating over a crop, seems one peculiarly suitable, and worthy of some trouble being expended to secure its adoption. By it, the whole of the nitrogenous materials of manure are secured for the soil. The urine that is voided on the earth is fixed in the soil as ammonia and remains available for future use. It is surprising how little of it escapes into the atmosphere, even on the top of a dunghill little ammonia is given off, though it is being formed in it to a large amount. Much less escapes from the earth which has the power of absorbing and retaining it. The droppings should not be removed from the soil, but allowed to remain on it, the rain will wash their nutrient properties down into the earth when they become converted into nitric acid by the rootlets of the crop, and are thus stored for future use. The crop which should be grown after the land has been thus treated will vary in different cases according to the character of the soil, but as a general rule, it may be laid down that the best paying *robi* or spring crop cultivated in that part of the country will be the one to sow.

* By Surgeon T. Hume, M.B., Amraoti.

With reference to fresh nightsoil as a manure, I have made some experiments, and find that in certain instances the result has been most satisfactory; the cases in which it failed, I will also mention as they may be of benefit to others. I had a large amount of nightsoil wherewith to experiment, viz., the daily outturn of a central jail containing 500 prisoners. This had always been thrown into deep pits in morhum, and was thus quite unavailable for all present or future use at the place where it was buried. Natives could not be induced to try it as a manure, and besides the almost insuperable objection they had on the score of caste, they insisted that it burnt up all crops, that it was too strong, &c. Despite these representations, I ordered the nightsoil—which had been mixed with about twice its weight of dry earth inside the jail—to be carried out into the garden, and there buried in trenches, from one foot to fifteen inches deep. The amount of the poudrette was six inches deep in the bottom of this trench, and over it a small basket of lime rubbish to each running yard was thrown. The whole was then covered over with the earth that had been excavated. In a month or two, I began cropping the ground, and raised on the first trial a beautiful crop of radishes—the large country radish, which are almost equivalent in bulk, I should say, to a garden turnip. I also tried it with bendikai with a like good result, as far as the experience of the plants was concerned, but the outturn of pods did not show such a marked improvement as the enlarged size of the plants would have led one to expect. The next crop I tried was carrots, and this was an unqualified success. Onions did remarkably well on this trenched ground; cabbages and cauliflowers were very luxuriant. Now for my failure—cotton; the trees grew to a great height, some of them being 6 and 7 feet high, but the crop of cotton from them did not correspond with this growth. The number of flowers was large, but the cotton while in the boll was attacked by an insect (a beetle) which lived on the seed, ate it out leaving nothing but the shell; and in different or destroyed cotton fibre was the result.

I am sorry that the above experiments were undertaken without any idea of their ever being reported, and that the crops have to base their claim to excellence on my opinion and testimony instead of having had their actual weights registered. Improvement to the crop and the utility of the manure there can be no doubt, as it was remarked by every one who saw the crops.

The point gained is the use of fresh manures, and that manure of the strongest nature. There is no doubt that this was attained by the lime rubbish which was buried with the latrine offal. I have seen the experiment recorded of some manure or putrescent substance which was treated with solutions of different kinds: one contained lime, one of the other was perchloride of iron. The substance to which the lime was added decomposed with the utmost rapidity. There is no further proof needed than this, and the testimony of experience that lime is the key by which the farmer opens and liberates the stores of nitrogen contained in manures, and in the soil. It served this purpose most effectively in those experiments of mine. While approving of the use of lime when applied to the soil, it is evident from what I have already said, the more you apply it the greater is the necessity to supply manures for it to work upon. I know of no more certain rapid exhauster of unmanured soil than lime. If therefore any attempt is made to utilise fresh nightsoil one indispensable concomitant is lime. I may here note an ancient belief with reference to lime which holds sway in the best farmed country in the world, that lime rubbish, i.e., old mortar which has been in a building for some time, is the best suited for such a purpose as I have described. I suppose that quick-lime is too rapid in its action, and overdoes the decomposing, forming chemical compounds not beneficial in large amount to plant life. Here, then, is an unused and valuable aid to manuring: if it is not a manure, but the lime of all old buildings is of service when put on land with manure.

Another lesson which these experiments taught me, or rather forced on my notice, is that those crops which come to maturity as a crop before they flower and seed, are much benefitted by this abundant and readily available store of manure, and

that those whose utility depended on their fruits, as bendikai and cotton, were not so benefitted. The over-luxuriance of the crop in the initial stage predisposes to premature decay whenever the period of growth is over, and hence the inability of those crops whose economic purposes begin to be developed after flowering, to resist the downward tendency. Manures, more intermixed with the soil, and more exposed, will suit these crops better than the fresh manure. Next year I have no doubt that this ground which has failed not to grow very fine seed crops. Small seeded crops, like radishes, carrots, mangold and cabbages which require in a short space of time to increase to a large size, require that there should be a large store of available manure to assist them in their rapid growth, while it is not so necessary in the case of slower growing, and smaller growthed plants like grasses, cotton, wheat, &c. This is the reason of the practice followed at home of giving manure to a green crop, such as turnip or potatoes, and not to a white crop such as wheat, barley or oats.

I have tried the effect of urine buried in trenches on a jowari crop, and found that it improved the crop, both straw and corn, in a marked degree.

The plan I can recommend for farm-yard manure and field refuse is a simple and efficacious one, which I commend to all who own stock and have fields. I dig a pit in the hard morhum four feet deep and about thirty feet square; into this I throw all the stable litter, cowdung, and the rank green vegetation that I can cut down in the compound till the collection reaches the top. I sprinkle over the whole of this a few baskets of lime and old mortar and cover it with a foot of black cotton soil. Of course any other good soil would answer the purpose just as well; it is put there to catch any ammonia that may be disengaged, and also to absorb any possible malaria that might be given off by the fresh vegetable matter during the early stages of decomposition. In less than six months the whole is as decomposed as manure need be, and fit for application to any soil, or for any crop requiring it. There is no loss of liquid draining away the soul and substance of the manure as it is retained in the rocky basin during the rains, and absorbed by the solid manurial substance during the cold weather. This means of converting the rank vegetation and weeds into a modification of one of the best manures we are acquainted with, viz., leaf-mould, is one that should be extended. By it the whole nitrogenous matters are preserved, whereas by the native plan of burning, only the saline matters are retained and given to the soil: the nitrogenous are dissipated by the heat.

I have not attempted here to give a dissertation on agricultural chemistry, as that has already been done by men who are much better versed in the subject than I am; the whole aim of this paper has been to be practical, and record what I have done for the guidance of those who may be inclined to try similar experiments.

There are numerous substances which if utilised as manure would be of immense benefit to the soil; but every one of these apparently available substances has some difficulty connected with it, in the way of its being employed. For example, the numerous dead carcasses of animals could, when made into compost, be used as manure. At present they are devoured by pariahs, kites and crows, and are not utilised as manure at all. But the rights of mahars (or pariahs) prevent this means of fertilising the soil being carried out. The hereditary privilege of eating carrion, the prescriptive right of gorging on animals that have died either a natural death, or from disease is not to be interfered with unless the pleasure of these lascivious repasts can be made up to them in some other way. Dead animals covered up with earth and left to decompose would be perfectly sanitary, and from them a large amount of nitrogenous manure, as well as phosphates, would be obtained.

The money value of this aforementioned plan of fertilisation is quite uncertain; it must vary much in different localities. As Government is the landlord, it must be from it that any regulations about rotation of crops must emanate. It can do this with all equity when it has ascertained what rotations are suited to various localities. In England no landlord would let his land without a definite agreement about

the cropping that was to be followed; he must do so to protect his land from exhaustion and himself from poverty.

The foregoing is a brief indication of the means by which this exhaustion of Berar soil may at once be remedied. The points of having a good grass for fodder which could be sown on the land which is now thrown fallow would benefit the cultivator, by giving him a fairly remunerative crop, benefit the land, that it, by its chemical actions, would store up nitrogen in the soil, the principal deficient plant-food in all of India, and allow the ground to be at once resumed as a productive cultivation area.

A FEW OF THE BOMBAY CENSUS FIGURES.

STATISTICS in some countries, and notably in India, are not only fearful and wonderful productions, in some respects passing all understanding, but in the hands of what now-a-days are called experts, and others who cannot be imagined to be experts, are made to perform feats of such astonishing dexterity as to bewilder and astonish even the very men who had a hand in conjuring them from the vasty depth of probability. Different men handling the same figures may so manipulate them as to evolve conclusions seemingly quite at variance from the natural conclusions lying on the surface, and so often does the warfare of controversy rage round figures, that it has passed into something like a proverb that "nothing is more misleading than facts unless it be figures." Statistics come to the bulk of mankind, unsophisticated mankind, in the guise of eternal verities, which it would be something near akin to an unpardonable sin to refuse to accept fully and unreservedly. They are supposed to be truth in a condensed form, truth winnowed of fancy and probabilities, truth at all events as it presents itself to the understanding and intellect of those who go down to the great depth where truth lies gulphed in the many waters that roll over its head. Men are beginning to realise, more forcibly perhaps in this than in previous generations, that their highest knowledge is but a great ignorance, and so, while the forcible power of dogmatic assertion grows less, the spirit of a wider toleration broods over the mass of cultured men. There are conditions at work in India which render the compilation of statistics in this country probably a matter of more exceptional difficulty to secure anything like results that will at all approach something near the truth. What these are, it is needless here to enumerate; they exist, and figures, computed with the greatest care, and after making every allowance for possible, probable and known contingences, are, after all, even in countries more favoured in this respect than India, approximations to truth rather than representations of the actual truth. The census of two years ago gave occasion for the compilation of statistics of all sorts on every conceivable subject connected with the people, and amongst the latest of these to come to hand is the operations and results of the census in the Presidency of Bombay, including Sind. We are bound to say that Mr. Baines—under whose supervision the work in that presidency was carried out, and whose two bulky and lucid volumes have just been issued from the Government Press—has grouped and reasoned from his figures with a masterly touch which does infinite credit to himself and the Government which he serves. Though this journal is nominally supposed to deal in matters statistical, it has come to be accepted that the statistics it deals with should have some bearing near or remote to the leading topic of its columns, *vis.*, agriculture. We therefore propose to place before our readers a few of the figures from the Bombay Census Report, so far as these have a connection with agriculture. One of the first general facts that strikes the reader of the results of the census operations in Bombay is, that the total population increased during the nine years intervening between the last and the previous census by 1·03 per cent only. The total increase is composed of a decrease of 0·28 in males, outweighed by an increase of females amounting to 3·48 per cent. This decrease of males and small increase on the whole population is of course due to the great famine which was felt over an area of 80,000 square miles in a population of over 30,000,000, and

which has left its mark in other directions besides those noticed above. There has been an increase in persons of both sexes above the age of thirty in all the worst famine districts, and in the case of women over fifty the increase is quite as marked as it is in the decrease of young persons under nineteen. This is easily explained by the fact that the males suffered most—more than females—in the worst periods of the famine and the following years, scarcity of food and insufficient nourishment made themselves apparent in a large diminution of births. The total number of persons engaged in agriculture, or dependent on those so engaged, is 10,015,477, but of these 52·5 per cent are at work, and the remainder supposed to be unoccupied. If Sind is omitted the agricultural population is 8,875,238, that is, more than 64 per cent of the whole population, and of these 4,753,602 or 54·9 per cent are workers. The ratio varies of course for the different divisions, but the figures given above are representative of the whole presidency. It may easily be conceived with what dire results a famine would be followed which fell among a populace more than half of which depended for existence on the gathering of a single harvest. This 64 per cent, directly depending on agriculture for a living, does not however represent the actual state of the case as it exists all over India. There is not a village tradesman, trader, or worker of any kind who does not depend more or less on the agricultural classes, because a very sensible proportion of their earnings is paid not in coin but in kind, and when harvests fail the agricultural population drag down to poverty and want all those classes dependent more or less on the wages received in kind from the ryots. It is the utter dependence of all ranks and classes of Indian communities on the safe gathering of the year's labours of the agriculturist that renders the failure of a single monsoon the herald of widespread poverty, ruin and death; and which, taking one year with another all over India, renders it imperative that the Government of India should be prepared to spend on an average yearly £2,000,000 sterling in famine relief, or on works which have an immediate connection therewith. We have probably said enough to render it evident that the great problem for Indian legislators is an agricultural one, if, indeed, the fact has not already in a hundred other ways made itself apparent. Population increases in a more rapid proportion than the land can supply food. The land of India is a known concrete factor, the population is an unknown quantity, ever increasing, checked at intervals by famine and its consequences. How shall outlets for this ever-increasing population be provided?—is the problem which must be taken up, and solved sooner or latter: the sooner the better.

THE CENTRAL PROVINCES.

THE report on the trade and resources of the Central Provinces for the year 1881-82, recently issued, is the first report of this nature that has been written by Mr. J. B. Fuller, since his assumption of the office of Director of Agriculture in those provinces, and is characterized by the thoroughness and completeness which were a feature in the reports issued by him when he was in the North-West Provinces. The report in question deals with the resources, manufactures, traffic communications and trade of the provinces, and some interesting information is given under each of these heads.

We see that the total area under crops during the year was 16,154,489 acres, of which 13,704,057 acres was under food crops, and 2,450,402 acres under non-food crops. Food grains occupy 84 per cent of the total area, and of these wheat and rice are the most important. Of the area under non-food crops, oil-seed and cotton occupy 1,557,661 acres and 666,031 acres, respectively; sugarcane 87,084 acres, tobacco 24,896 acres, fibres 31,009 acres, and vegetables 48,626 acres. There has, we observe, been a gradual increase in the total area under crops during the

past three years, the crops which show the largest increase during that period being wheat and oil-seeds. The area under rice which, during 1881-82, is shown as 4,039,555 acres, has been almost stationary during the last three years, and that under the coarser grains has declined a little.

The chief minerals of the provinces are said to be coal, iron, and the stone and lime of the Jubbulpore district. The output of coal at the Mohpani mines, which are worked by the Nerbudda Coal and Iron Company, was, during 1881, 10,454 tons, the royalty paid to Government for that period amounting to Rs. 1,819. The coal beds at Warora are, however, of more importance, the output of during coal 1881-82 having been 68,156 tons against 25,696 tons in the preceding year. We see it stated that extensive coal fields have recently been discovered at Muaria, in Rewa territory, 34 miles across their northern boundary, and are believed to extend into the northern portion of the Jubbulpore district. It appears that the Betul district has also been credited with coal beds which have been the object of extensive boring operations during the past two years. The Geological Department selected three sites for the sinking of bore-holes to the depth of 400 feet; the work has cost Rs. 11,096, but the results are reported to be unpromising. A fourth site has, it seems, been selected for deeper boring in the hope of striking richer strata.

Iron is not yet worked on an extensive scale. It is said that there are about 48 small iron mines in the hills to the north of the Jubbulpore district, while several mines are also to be found in places in the Saugor district, which, during the year, yielded 36,863 maunds of ore. Referring to the iron of the Chanda district, which was formerly a native industry of some importance, it is reported that the resources of the district have recently been investigated by Mr. Ritter von Schwartz, a gentleman of considerable experience in iron working in Austria. His report has, it appears, been a favourable one, and is now under the consideration of Government. Mr. Schwartz thinks that "with the construction of proper furnaces, there would be no reason to doubt the possibility of Chanda turning out a very large quantity of iron or steel, and that an export trade to Europe might even be opened in certain articles now imported from the continent, such as ferro-manganese and Brescia steel."

The amount of stone quarried in the Jubbulpore district during the year is returned as 391,050 cubic feet, particular mention being made of a quarry which yields a stone of some value for the manufacture of chocolate paint. We observe that the lime excavated at Murwara is said to fetch a high price in the Calcutta market; the amount quarried during the year was 160,416 cubic feet, for which as much as Rs. 48,125 was realised.

Turning to the manufactures of the provinces, we see that the cotton mills occupy the most prominent place therein. During the year under report, the amount of raw cotton worked up was 33,895 cwts., the amount of twist manufactured 1,804,530 lbs., and the amount of cloth manufactured 1,491,945 lbs. The value of the cloth and twist is put down at Rs. 1,593,864. The Nagpore and Hinghunghat cotton mills are reported to be in a very flourishing condition, the outturn of the former having greatly increased during the last two years owing to the introduction of the electric light which allows work to be carried on both night and day. Cotton mills are also about to be established on the Nerbudda, where it is intended to utilise water-power for working them. Among the handicrafts of the provinces, weaving, metal working, carpentry, and the manufacture of gold lace and silk goods, appear to be the most important. The report says that "the cloth of Chanda is reported to have been of extraordinarily good quality, and at the commencement of the century was exported as far as Arabia. Similarly the brass-work of the town of Bhundara, of Lodhikhera in Chindwara, and of Hurda in Hoshungabad bore an excellent name, and the Chanda and Jubbulpore districts were noted for the manufacture of durable utensils from the iron which is found within their limits. It is universally reported that both the weaving and metal working industries have suffered

severely from the competition of European goods. Cotton cloth and metals constitute the principal return which England makes to these provinces for the grain and oil-seeds which she draws from them, and the value of articles included under these two heads amounted to 40 per cent of the total value of the imports by rail during the year under report. It is not therefore surprising that from every district there should come the same account of declining profits, of the emigration of the artisans to places further from the railway, or of ruin daily averted by a change of trade. The decline commenced "with the substitution of English materials for those fashioned by native craftsmen. Thus, rolled sheet brass came into use in Bhundara and Lodhikhera in place of that beaten out of by hand, and English cotton yarn was preferred by native weavers to that locally spun." A curious and interesting feature in the manufacture of lace at Burhanpore is the drawing of silver-gilt wire of astonishing fineness from a bar of silver, called a *passa*, which is lightly or heavily gilt as the occasion requires. The report says that "the *passa* is of a uniform weight of 60 tolas, and its manufacture and the preliminary process of wire-drawing are conducted under municipal supervision, and made the source of a small income, a duty of Rs. 1-8-0 being levied on each *passa*. The weight of gold-leaf to the *passa* varies from 4 to 42 *mas*. A *passa* is often drawn out into a wire 72,000 yards in length, and the length of wire per tola of weight varies between 500 yards (for gold lace sold by weight) and 1,200 (for spinning the thread of mixed silver known as *kalabathe*.)"

The following figures will give an idea of the extent and value of the trade of the provinces during the year. The imports by railway amounted 39,97,867 maunds, valued at Rs. 3,58,89,598, and the exports reached 1,64,93,192 maunds, valued at Rs. 4,75,11,826. The imports consisted of coal, cotton goods, fibres, metals, salt, spices, sugar, and tobacco, while among exports we find coal, cotton, fibres, wheat, *ghee*, linseed, teelseed, and other grains. The railway trade is distributed between the East Indian, Great Indian Peninsula, Warda Coal, Nagpore and Chhattisgarh, and Rajpootana-Malwa Railways.

The total weight and value of the trade with the adjoining native territory is shown as follow :—

| | Maunds. | Value. Rs. |
|---------|---------------|---------------|
| Imports | ... 10,41,776 | 48,37,641 |
| Exports | ... 7,82,237 | 49,52,358 |

The principal items of import are cotton, grain, opium, *ghee*, and oilseeds; and the export trade is confined to cotton goods, grain, metals, spices, and sugar.

THE ARTESIAN WELLS OF PONDICHERRY.

THE Government of Madras has recently published some interesting notes by Deputy Surgeon-General Furnell, the Sanitary Commissioner for Madras, on the artesian wells of Pondicherry. Dr. Furnell's visit to Pondicherry was to make himself acquainted with the artesian well water-supply, as well as to ascertain the extent to which the cholera epidemic of 1881-82 had affected the settlement. Dr. Furnell tells us that, in his capacity of Sanitary Commissioner, he is chiefly interested in artesian wells as affording a water-supply for domestic use, and that whether they are useful for irrigation purposes or not, is a question which does not concern him, except indirectly. We observe, however, that their inutility as a means of irrigation has been conclusively settled by the local Public Works Department.

It is stated that there are now about 14 artesian wells scattered over the town of Pondicherry and its neighbourhood, and that in different parts of the settlement fountains, with water laid on from these wells, give an ample supply of good and pure water for the use of the people. In his remarks regarding the different strata encountered in the

construction of these wells, Dr. Furnell says that at the Sarana Cotton Mills, he was shown a number of sectional diagrams of the borings which were "ingeniously constructed, showing the actual strata in position, not drawings, but the sand, laterite, argillaceous sand, &c., themselves in situ," and that he was much struck with the various and dissimilar strata of the different borings. In some wells he observes that the "principal strata are alternate layers of gravel mixed with clay, lumps of black plastic clay, coarse blackish sand, mixed with black clay, &c."; while in the one situated in the town itself, which he inspected, "the strata were all more or less of hard, almost impenetrable material, thus described—quartz, argillaceous sand, coal, sable gros grains, quartz, lignites, débris des roches primitives, minerais-de-fer, laterites gris ferrugineux, &c." This particular well is said to have been commenced on the 16th August 1879 and completed on the 27th September 1880, at a cost of only Ra. 1,000. It was bored to a depth of 82 metres or 338 feet, and the result is said to be an abundant supply of good water. Dr. Furnell's remarks regarding the nature of the water are interesting. He says that "it is warm, clear, with a distinctly ferruginous taste. It is used by the natives for cooking and drinking, and its slightly ferruginous taste comes to be liked after a short time. It is in high repute medicinally; skin affections are said to disappear under its use, and many natives of respectability come from English territories to drink the water for diabetes; indeed, lately at Madura I met a highly intelligent Brahmin gentleman, who informed me he had been residing in Pondicherry for some time to drink these waters for an affection of the kidneys, and had derived much benefit therefrom." The analysis of a sample of the water from an artesian well has been given as follows by the Chemical Examiner to the Local Government:—

| | | | | |
|---------------------|---------------------|-----|-----|-------|
| Total solids, | grms. per litre | ... | ... | 0.43 |
| Volatile solids, | do. | ... | ... | 0.12 |
| Sodium chloride, | do. | ... | ... | 0.047 |
| Total hardness, | Clark's scale | ... | ... | 9.8 |
| Permanent hardness, | do. | ... | ... | 2.8 |
| Free ammonia, | mlgrms. per litre | ... | ... | Nil. |
| Albumenoid Ammonia, | do. | ... | ... | 0.02 |
| Nitric acid, | do. (as ammonia)... | ... | ... | 1.2 |

Remarks.—A good water.

As regards the cost of the wells, it is stated that those at the Sarana Cotton Mills have cost about Ra. 2,000 each; others have cost Ra. 500, while it is added that "a native in Pondicherry is very willing to undertake sinking wells on a salary of Ra. 150 for himself per month, finding the machinery, but of course not paying the coolies, the pay of whom must be defrayed by the person employing him."

In the report on artesian wells furnished to the Madras Government by his Excellency the Governor of the French Settlements, the notes collected in connection with the most recent borings made by the Government, as well as those made by the Civil Engineers, are also supplied. It appears that seven artesian wells have been bored since August 1880. We select one which was constructed in 1881 at the Sarana Cotton Mills; it was bored between the 26th March and the 27th April 1881, and the following notes, recorded by the engineer who executed the work, may not be uninteresting to our readers:—

| | | | |
|---|-----|-----|-----------------|
| Height of the soil above the mean level of the sea... | ... | ... | 3.20 metres. |
| Depth of the well in the soil | ... | ... | 26.20 " |
| Diameter of the orifice at its outlet | ... | ... | 0.18 " |
| Discharge of water per minute at 0.20 centimetres above the soil on the 20th April 1881 | ... | ... | 200 litres. |
| Temperature of water at the orifice of outlet | ... | ... | 32° centigrade. |
| Hydrostatic degree of water | ... | ... | 10° |
| Hydrostatic level of the spouting sheet of water above the soil | ... | ... | 1.00 metres. |
| Hydrostatic level above the mean level of the sea | ... | ... | 4.20 " |

During the execution of this work, the sounding lead met with a series of the following layers:—

| No. of layers. | Composition of the ground traversed. | Thickness of layers. | Depth of layers. | REMARKS. |
|----------------|--|----------------------|------------------|--|
| | | M. | M. | |
| 1 | Ground lately embanked | 0.27 | 0.27 | |
| 2 | Vegetable earth | 0.25 | 0.52 | |
| 3 | Brown and blue clay | 0.25 | 0.77 | |
| 4 | Clay marbled with reddish, yellowish and greyish spots with a mixture of sand and carbonate of lime | 0.55 | 1.32 | |
| 5 | Sandy clay with veins of yellow, brown and some garnets | 0.40 | 1.72 | |
| 6 | Large size sand, soiled with brown clay | 0.30 | 2.02 | m. 2.20 level of sheet of water of surrounding wells. |
| 7 | Large size sand with clay | 2.50 | 4.52 | |
| 8 | Large size bluish sand, mixed with small pebbles and refuse of rotten wood, pieces of plastic clay, rolled up pebbles, basalt, and amphibole | 2.08 | 6.60 | |
| 9 | Grayish fluid sand and mica mixed up, agglomeration of black clay, basalt and amphibole | 0.50 | 7.10 | |
| 10 | Grayish black thin sand, black spots, (titanate of iron) agglomerations of black clay, basalt and amphibole | 0.50 | 7.60 | |
| 11 | Black plastic clay, broken up shells, refuse of rotten wood | 4.70 | 12.30 | |
| 12 | Medium size sand and also fine, soiled by black clay, bits of shells, refuse of rotten wood | 1.00 | 13.30 | 1st ascending sheet of water, 1st April 1881, at 8½ o'clock morning; hydrostatic level of sheet of water, m. 3.20 of the soil. |
| 13 | Bluish earth, large and medium bits of shells, refuse of rotten wood | 3.90 | 17.20 | 2nd ascending sheet of water, m. 0.35 above the soil. |
| 14 | | | | |
| 15 | Black plastic clay | 5.30 | 22.50 | |
| 16 | Black sandy clay | 0.50 | 23.00 | 3rd ascending sheet of water, level of the soil. |
| 17 | Black plastic clay | 1.50 | 24.50 | |
| 18 | Medium size sand with mica soiled with black clay | 0.50 | 25.00 | |
| 19 | Medium sand, mica, soiled black clay | 0.60 | 25.60 | |
| 20 | Large size bluish sand (basalt and amphibole) shells, broken pieces of bricks, bits of shells, refuse of rotten wood | 0.60 | 26.20 | |
| 21 | | | | |

The spouting sheet of water was met with at the depth of m. 26.20 in a layer of bluish large-grained sand mixed with pebbles, some small shells, and rotten wood. Its hydrostatic level rose to m. 1.00 above the soil, and its discharge of water on the 20th April 1881 of 200 litres per minute.

SERICULTURE IN THE DOON.

IN the last administration report (1881-82) of the Agricultural Department of the North-West Provinces and Oudh, some interesting information is given regarding the prospects of sericulture in those provinces. We learn that the enterprise is now in the hands of Messrs. Lister and Co., of Bradford, whose manager, Major Murray, has already done a good deal to push on operations on the lands which have been granted to the firm in Dehra by the Government of the North-West Provinces and Oudh. It is stated that 50,000 seedling mulberries and four acres of cuttings—of both the *sinensis* and *multicaulis* varieties—are now on the Song grant, and that a canal measuring 4½ miles has been dug for the purposes of irrigation. It is pointed out, however, that one of the chief draw-backs which Dehra offers as a centre for sericulture is the want of leaf. A very small supply appears available at present, and it was owing to this deficiency that a good portion of the silkworm seed put down by Major Murray during 1880-81 had to be thrown away. During the year 1881-82, "12 ounces were put down, and even then there was not enough leaf for night feeding, though the trees were stripped for three miles round. Moreover, the roadside trees, not being manured or tended, threaten to give a continually diminishing supply."

Cottage cultivation does not appear to have been very successful. The production of silk by villagers during the official year 1880-81 amounted to 12 maunds 24 seers green, for which they were paid at the rate of Rs. 40 per green maund. In the Punjab, it is stated that the same quantity obtains Rs. 16, Rs. 20, or Rs. 24, according to quality, while in Calcutta a maund of dry silk fetches from Rs. 80 to Rs. 100, and is really equivalent to three green maunds. In the face of these rates, the report goes on to say, that to pay Rs. 40 for a maund of green silk must result in a loss to the purchaser. During the year under notice, the price offered to the villagers by the firm was Rs. 20 per maund, but only two cultivators were found to agree to these terms, the quantity of seed taken by them amounting to 4 ounces, which gave a produce of ten seers of silk to the ounce. Notwithstanding the obstacles which the firm have had to contend with, it is satisfactory to learn that they hold the opinion that "Dehra offers a very fine field for the cultivation of healthy seed, and that if a remunerative price were guaranteed, an almost inexhaustible supply might be depended on." In connection with this matter, an important question suggests itself to the Agricultural Department, which seems deserving of attention. It is whether the importation of healthy seeds by silk-growers in the Bengal presidency, while helping to augment the supply in the Doon, might not also serve to revive the silk industry of Bengal. The difficulties which, it appears, at present obtains in the way of providing supplies in the manner indicated, is due to the fact that Messrs. Lister and Co. are at present the only silk-growers in the Doon, and it is thought that they might not care to undertake the enterprise. It is stated, however, that the matter has been brought to their notice in view of eliciting their views thereon.

What is chiefly wanted to make sericulture successful in the Doon is mulberry trees and rearing accommodation. As regards the first, the report says that "the initial difficulty is that trees to be of any use must be within a short distance of the rearing sheds. It hardly pays to carry them three miles, and certainly not further." The land near Dehra is already taken up by crops and gardens, and is so extremely valuable that it is doubtful whether to plant it with the mulberries, which might after all never be used, could be justified. To plant trees in the jungles is to anticipate on insufficient grounds the locality which a future silk enterprise might select. The forest department, who were addressed with the view of establishing mulberry plantations, offered the sites of two deserted villages at a distance of about 24 miles from Nynsee-Tal, and not nearer any other possible commercial centre. The cost would

have been Rs. 7,000, and the trees would have been of no use whatever except for silk working. This offer we see was declined by Messrs. Lister and Co., and the project was abandoned. Arrangements, however, it appears, have been made with the Superintendent of the Doon that a small garden at Dehra should be planted out with trees, and it is stated that further proposals are under the consideration of Government, which involve both the growth of mulberries and the provision of proper rearing sheds for cottage cultivation. The report mentions a second silk concern which has been started in the Doon by Colonel Utterson, but at present it cannot be depended on for seed.

EDITORIAL NOTES.

BEE-KEEPING in India has never gained a footing among the paying industries, and the Government of India think there is no prospect of its being made an important source of remuneration to the labouring classes, even if they take up the matter seriously, and place facilities in the way of encouraging the natives, who alone could undertake bee-culture in this country. The chief obstacle to giving bee-keeping an impetus is the want of a sufficiently large and influential staff of officials competent to instruct the natives, and interested themselves in the matter. Perhaps the only practical bee-keeper in India is Mr. John Douglas, of the Telegraph Department, who is not unknown as such to both the Home and Indian Governments. Bee-culture is not quite unknown in the upper provinces, and in some small tracts of the southern presidency of India. But the mode of keeping bees here has been of a most primitive type, and not calculated to encourage the extension of the industry, for the returns for labor are small; and only such as have had time and little trouble have interested themselves in it, and have utilised the outcome of their labors mostly in home consumption. The same may almost be said of the bee-keepers of the Himalayas, who, after providing for home use, retail the balance in the bazaars of our various hill sanitariums. In Cashmere, however, we may accept it, on the authority of Mr. Moorcroft, that the bee is domesticated, and its produce calculated upon as the harvest from an acre of land. There, its domestication appears to be complete, and in some parts of the territory a provision is made for beehives during the construction of the houses of the people. According to the system in Cashmere, the hiving and abstraction are done in the simplest form—the latter by the smoke of a smouldering wisp of straw introduced into the hive, and so well provided for are the inmates of the hives in the matter of accommodation, that shortly after being deprived of their hoard they are induced to return and commence collecting another store. It is a common thing for the same colony of these insects to produce honey year after year in the same hive for several generations. They have been literally domiciled with man for so very many years, the bees of Cashmere have the reputation of being "milder in their manners than those of any other country" (so the papers of the Agricultural Department tell us), although they are said to have "a most villainous sting," and Mr. Moorcroft tells us that their produce is "as pure, clear and sweet as the finest honey of Narbonne." The Indian Government, under the guidance of the Agricultural Department, sees enormous obstacles to the introduction of the bee industry into this country, stating that there exist no natural resources for the subsistence of the bees on the plains. But one would ask, why a hive depot could not be established at each hill station in India where there is always a large growth of indigenous flowers, &c., and by which the objection of the Government would be removed. Mr. Buck expects to have some important information afforded him on this subject at the forthcoming International Exhibition in Calcutta, and till then the question has been shelved. As other more important subjects will occupy the Government at the Exhibition, it is not likely this will be given a thought to, especially as it was received from the first in a half-hearted manner. Mr. Douglas went to much trouble in collecting information on the feasibility of establishing bee-culture in India, and as an expert in the matter is hopeful of its success; but the Government of

India—perfectly unacquainted with the subject—finds numerous objections, which, if it were disposed to favour the industry, could easily be removed. But the Agricultural Department, apparently knowing nothing of the matter, discountenances the scheme, and it therefore, receives no support from the Government of India.

The report of forest administration in the Central Provinces during the year 1881-82 shows that the forest area at the disposal of the local administration, at the close of that period, was 19,719 square miles, as against 19,666 square miles at the end of 1880-81. The total area is divided as follows:—

| | | | |
|-----------------------|-----|-----|--------|
| First class, reserved | ... | ... | 2,588 |
| Second | ... | ... | 16,842 |
| Unreserved forests | ... | ... | 289 |

The total number of forest offences during the year is stated as 9,228, or almost double that of the foregoing year. The report, however, explains that "it must not be implied that there has been any increase in the number of offences, or any greater tendency to disregard the forest law, but there can be no doubt that the record of cases reported has been more complete, and that, on the whole, the arrangements for watch and ward have been better." In the first class reserves there were 451 cases of breach of forest rules. In 21 cases prosecuted, 18 resulted in convictions; in 3 cases the offenders were not detected, and in 427 cases the persons were allowed to compound. In the second class reserves the offences amounted to 8,779. The cases prosecuted were 777, of which 716 resulted in convictions; in the remaining cases the persons concerned were allowed to compound.

The results of fire protection do not appear to have been very satisfactory. The area attempted during the year was 904,582 acres, as against 924,380 in 1880-81, while the area actually protected was 773,893 acres, as compared with 869,828 acres in 1880-81. The proportion of failures to the area attempted was, therefore, 14 per cent as against 6 per cent for the preceding year.

The cultural operations of the year have not been very extensive, having been confined to two divisions principally; for one, the minor division, the expenditure amounted to Rs. 4,137, while the different works undertaken were the cultivation of a stock of fruit trees at Girgaon, the raising of evergreen trees along the boundary in the Kandwa reserve, the maintenance of the Girgaon nursery, and the pitting of land, and planting out. The plants put out were teak and bamboo, but it is feared that only a small proportion have succeeded well. In the Saugor division the expenditure, which amounted to Rs. 2,074, was spent on maintaining nurseries, the protection and cultivation of a field of 50 acres sown in the previous year with bamboo, the fencing of bamboo previously put out, and the putting out in the natural forest of 67,000 bamboo clumps, of which 27,600 are reported as successful.

The financial results of the year show, we observe, a great improvement as compared with the figures for the year 1880-81. The revenue derived has amounted to Rs. 11,72,884, against Rs. 8,50,139 in 1880-81, while the expenditure was Rs. 4,97,013, or only Rs. 1,500 more than it was in the preceding year. Of the total revenue, Rs. 3,10,176 represents the receipts on account of the timber operations of the year.

The following letter from W. R. Robertson, Esq., Agricultural Reporter to the Government of Madras, to W. Wilson, Esq., Director of Revenue Settlement and Agriculture, Madras, dated Saidapet, 15th April 1883, and endorsement by the Director of Revenue Settlement and Agriculture, has been printed by the Madras Government:—

I have the honor to suggest that the undermentioned Aden stock might with advantage be imported:—Fifteen young bulls; six cows, each with a bull-calf at foot. Our last importation of this stock in 1881 consisted of—Two bulls, four cows, and four calves; and the entire cost of the importation was Rs. 900-5-3. The average cost per head would thus be per bull Rs. 150: per milch-cow, with calf, Rs. 150. At the foregoing rate the animals I now propose should be imported would cost here Rs. 3,100.

The bulls should be about three years of age and the cows not over 4, each with her first calf which should be a bull-calf. Preference should be given to animals suited as dairy stock. The importation should not, I think, be made until the south-west monsoon is over. It would, I think, be best to send two farm laborers to Aden to receive and look after the cattle on the voyage here; this course would not be more expensive than that followed on the last occasion, when two Arabs accompanied the cattle here, and afterwards returned to Aden.

Numerous applications have been received from different parts of the Presidency for the loan of Aden bulls for use in improving local dairy stocks. It seems very desirable that these applications should be met. We will shortly have some Aden bulls available at the farm for stationing in some of the districts, but the number is small.

If the foregoing proposals are approved, I suggest that the bulls available at the farm next cold season should then be distributed. The bulls to be imported should, I think, go to the Saidapet Farm until they have recovered from the effect of their voyage, when such of them as are then fit might also be distributed for use. The cows I would keep at the farm until the up-country Experimental Stations are opened, when one cow and a bull also might be sent to each station.

THE endorsement on the above, submitted, through the Board of Revenue, for the consideration and orders of Government, is as follows:—

"The Aden breed of cattle has been much admired by the deputations of ryots who have visited the farm from different districts. They are peculiarly docile and good tempered, while possessing every quality that can be desired for purposes of draught. They are of medium height, and the bulls would therefore serve admirably for the improvement of the small, and too often poor, breeds that are to be found in many districts of the Presidency. Mr. Robertson's suggestions are, therefore, recommended for sanction.

The Farm Budget for the current year provides only Rs. 1,500 for the purchase of live stock, and the required funds would have to be provided by supplement from the Agricultural reserve. Passage for cattlemen to and from Aden and the cost of fodder and freight for the cattle from Aden must be added to the estimated price of the bulls and cows; the probable amount of these items will be ascertained and reported.

THE following is the Government resolution on the subject of Bee-keeping in India:—

In November 1881, the Government of India was furnished by the Secretary of State with copy of a correspondence with Mr. John Douglas, of the Indian Telegraph Department, then on leave in England, on the subject of bee-keeping in India. Mr. Douglas, who had studied the industry as followed in Europe with a view to its introduction into this country, desired to be supplied with information regarding the varieties of honey bees indigenous to India, and the results of past efforts towards their domestication, extent of the demand for honey, the quantity produced, and the prices realised. In forwarding the papers, the Secretary of State remarked that the subject appeared to be of sufficient practical interest to engage attention. Local Governments and Administrations were accordingly requested to furnish such information as might be available on the subject.

The replies received comprise a large number of interesting reports by Forest and District officers and other persons who have paid attention to the subject. As the information may be useful to the naturalist or the bee-keeper, the reports have been printed, and will be made available to the public. The broad conclusions to be drawn from their perusal are—(1) that several varieties of honey-bees are found in every province of India where there is sufficient forest of jungle, and that the honey of some of the varieties is good and in considerable demand; (2) that efforts have been successfully made in the hills by Europeans to domesticate Indian bees, but that bee culture is only practised by natives in the very rudest way; (3) that it is very doubtful whether the bee could be domesti-

cated in the plains owing to the dearth of flowers during the three or four months preceding the rains; (4) that in Southern India persons (Mr. Stormont of Bombay and others) have given up all attempts to domesticate the most common variety of bee found there on account of its intractable nature.

The industry is unlikely ever to be one of great importance in India. It can only be followed in the hills, where flowers abound throughout the greater part of the year, or in forests, where food is equally plentiful. In the populous country of the plains, bee-keeping as a general industry seems impracticable. Under these circumstances, there is little or no call for action on the part of Government. Such action could only assume the form of improving the system of bee-culture in the hills and forest region, but the Government of India does not at present see its way to taking any practical steps in this direction. Opportunity will, however, be taken of the Calcutta International Exhibition to make some further enquiries in the matter. With this object, Local Governments and Administrations are invited to authorize their respective Agricultural Departments, &c., to forward to the Exhibition specimens of honey, naming, if possible, the variety of bee by which it is produced, and the specimens will be submitted to examination by experts.

From the experiments that have been made on the Cawnpore Farm, there is some hope of sorgho superseding the cane at some future period. The plant possesses three advantages over cane. The first is, that it yields a grain fit for human food; second, it makes excellent fodder for cattle; and third, it occupies the land for only four months of the year, while cane takes it up for a whole year. Then, in addition to this, sorgho requires scarcely any manure and no irrigation. Every one will admit these as considerable advantages over the cane; but the difficulty with sorgho is in the manufacture of the sugar, and this is where the experiments of the first year were unsatisfactory. Three varieties of the plant were tried during last year, the amber and the red descriptions producing a somewhat less proportion of juice and *goor* to the whole plant than uncleaned sugarcane; but rather a larger proportion than the cleaned cane. The *goor* manufactured from the sorgho, though it had a peculiar acidity, was well-flavored, clean, and commanded a higher price in the market than that produced from cane. It appears to have a good future before it for eating and various manufacturing purposes. When the farm officers procure improved machinery and have taught the natives how to cultivate the plant, to manufacture *goor*, and put it to other paying uses, then perhaps the expectations of the Agricultural Department of the N.-W.P. and Oudh may be realised in regard to the superiority of this plant over cane as a sugar-producer.

A VERY large trade is done in the Central Provinces in wood, principally teak, which is so plentiful in Nagpore and adjoining towns that it is used even in the most common carpentry for the most trivial want. I do not know, says a correspondent any reason why the Central Provinces should not supply a great portion of this wood to the markets of the world, and why Burmah should have the monopoly of supply, when there are hundreds of square miles of teak wood available in these territories, size and quality equal to the best Moulmein. Thousands of squared beams are brought in from the outlying forests from 1 to 2 feet square and sold at an average of from 8 annas to 12 annas per foot, and as the cost of carriage from here is dear, are wasted principally in supplying sleepers to the railways. Such misuse should be officially prohibited at once, more especially as great forests of the other strong and durable woods exist, chiefly *sal*, more convenient to the railway lines than the supplies of teak. Besides the supply brought to his doors, the railway contractor has the pernicious habit of selecting the most convenient trees from 10 to 12 inches in diameter in forest tracts—those that will split up into 4 or more longitudinal sleepers—which, if left, would rapidly acquire dimensions of five to six feet in depth. So ruthlessly is his work prosecuted, that whole forest areas, which

are generally of one age, take only a few seasons for the tree to become totally extinct. If the railways reduced their rates for the carriage of this wood, I am positive that at once sufficient quantities would be transported to Bombay, and that the high prices ruling for Burmah wood—the monopoly of one or two firms—would at once have a fall. When the through railway is a *fait accompli*, your market will certainly be supplied. I think it is the imperative duty of the Government to stop, and at once, the ruthless destruction of the tree, and take all forests, whether feudatory or otherwise, under their protection; conserving them, and at the same time making their wealth available in an intelligible and imperial disposition, not treating these forests and their produce in the spirit of petty paddling and huckstering prevalent in this province. A certain amount of large trees should be felled each year at the different forests; or contractors, on paying the authorized demand, should be allowed, under direction, to fell for themselves and take away the logs; and for every tree thus cut three seeds or seedlings should be put down. I would venture to state that were this advice systematically carried out by the State, the Central Provinces alone would for ever supply the wants of the world in this wood. There are, say, taking a low calculation, from 3½ to 4 millions of large available teak trees on British and feudatory territory, in Pannabarras, Bustar, in the Raepore and Chanda districts and at Allapilly (in the latter the most superb trees have been viciously destroyed by some Forest Department officials in their zeal to supply sleepers to the Nagpore State line); and if, say, 20,000 logs were annually cut down, in a hundred years half the useful wood will have been felled, and in the meantime a supply would be ready from the systematic sowings. But besides Government have at this time well selected reserves, many square miles in area, in which teak trees of all ages, from saplings to 10 to 30 year old trees, exist in inexhaustible numbers, and before the hundred years we have allowed, expire, these would be available to supplement the recognised store;—such is the source from which, I say, if judiciously conserved, an annual supply of teak can be drawn—practically unlimited.

THE results obtained last year, says the *Farmer's Review*, in the production of sugar from the sorghum plant on a commercial scale, and affording a profit to both the grower and manufacturer, were such as to practically settle the question in favor of sorghum as a profitable sugar producing plant. These results were but the culmination of long series of experiments and careful study, which have extended over a series of years in various parts of the country, during which time the character of the plant and the influence of climate, soil and cultivation upon its juices, have been carefully studied, and its juices, subjected to careful analysis, at various stages of its growth, to determine the particular stage in which they reached their maximum saccharine quality, and also to discover those properties which hindered the crystallization of the sugar contained in them, and how they can be effectually removed.

All these problems seem to have been solved, as shown by the success attending the sugar production from sorghum cane at Rio Grande, N. J., and Champaign, Ill., during last year. It had already been demonstrated that syrup of a superior quality and of a high commercial value could be produced. But successful sugar production on a commercial scale had never been achieved until last year. Previous results in crystallization, which had been common, were accidental, and could not be relied upon. The importance of this question of domestic sugar production to the country, and especially to the farmer who must be relied upon to grow the cane, can hardly be appreciated. Its economic importance can best be shown by the amount and value of the sugars annually consumed in this country and the proportion of them we are dependent upon foreign supply for. The consumption of sugars in this country is said to be 44 pounds per capita of our entire population, which by the census of 1880 was in round numbers 60,000,000. Estimating our present population at 55,000,000 and on this basis our yearly consumption of sugar reaches the enormous amount of 2,420,000,000 pounds, or 1,210,000 tons, enough to load 80,666 railroad cars of 15 tons each, which, if stood in a line on single track, allowing 33 feet

to each car, would form a continuous line of 623 miles. This, it will be understood, includes sweets of all kinds, having a sugar as a basis. Of this amount, our total domestic production, including Southern cane sugar and molasses, sorghum sugar and syrup, and maple sugar, does not exceed ten per cent of our yearly consumption. During the fiscal year ending June 30 1881, the value of our imports of sugar, molasses, melado, confectionery, &c., as shown by reports of the treasury department, amounted to \$94,782,104. The duties collected upon the same amounted to \$47,986,041, making the total cost of the importations for the year \$142,768,145. Of this amount, nearly one hundred million dollars was paid to foreign sugar producers. The sorghum question involves nothing less (if satisfactorily solved) than the saving of this amount to the country and transferring it from the foreign grower to the American farmer and sugar manufacturer, for, as we shall show in future articles, the work of domestic sugar production from sorghum must be divided between the farmer who grows the cane and the manufacturer who converts it into sugar and syrup.

MR. THOMAS JAMIESON, F.I.C., F.C.S., chemist to the Sussex Association for the Improvement of Agriculture, has published a full and exhaustive report, giving an account of experiments conducted last year. The first part of the report deals with wheat-growing, the noteworthy facts elicited in connection with this being, that a moderate increase in the yield followed from the use of farmyard manure, and that the profit is nearly doubled on the plots judiciously treated with artificial manure. Artificial manures containing nitrogen were found to give a great increase, and Mr. Jamieson holds that the use of these need not exhaust the soil. The following mixture was found to give the best yield of wheat in Sussex last year. In autumn, before sowing and harrowing in the seed, a mixture was given containing per acre $\frac{1}{2}$ cwt. sulphate of potash, $\frac{1}{2}$ cwt. sulphate of lime (these might be substituted by 1 cwt. ground kainite), $\frac{1}{2}$ cwt. ground coprolite flour (not gritty nor brownish), $\frac{1}{2}$ cwt. steamed bone flour (as fine as wheat flour, or nearly so), $\frac{1}{2}$ cwt. nitrate of soda. In spring, say March, $\frac{1}{2}$ cwt. sulphate of potash, 1 cwt. mineral superphosphate, $\frac{1}{2}$ cwt. steamed bone flour, $\frac{1}{2}$ cwt. nitrate of soda. Mr. Jamieson strongly recommends farmers not to purchase these substances mixed together, nor indeed any mixture (under the name of wheat manure, mangold manure, champion manure, &c.), but to purchase the ingredients separately, and mix them for themselves. Experiments on roots brought out results similar to those of the Aberdeen Agricultural Association, namely—that undissolved phosphate has proved equal to the dissolved phosphate. The manure recommended for roots is contained in the following mixture for soil assumed to be very deficient in all the essential ingredients:— $2\frac{1}{2}$ cwt. coprolite flour, 2 cwt. steamed bone flour—to provide phosphorus; $\frac{1}{2}$ cwt. nitrate of soda, $\frac{1}{2}$ cwt. sulphate of ammonia, $\frac{1}{2}$ cwt. horn dust or dried blood—to provide nitrogen; 2 cwt. kainite, ground—to provide potash. Under the division of analytical plots, the report says:—

"We now come to what I regard as the most interesting part of the work this year at this station—to results that may ultimately have an important bearing upon the economy of manuring. It will hardly be possible, however, to err by an excess of caution in forming conclusions from these results, until they are well confirmed. Briefly—but I state it under reserve—they imply a reduction of the essentials of plant life; they appear to show that the mineral ingredients deemed essential to plants may be a much simpler group than the seven-sided one at present accepted; that the whole subject of manures may be simplified; and that much useless expenditure in manures may be spared. We have all—agricultural chemists without exception, I believe—accepted as fact that a complete plant cannot be formed in the absence of any one of the seven mineral ingredients—nitrogen, phosphorus, sulphur, lime, magnesia, potash, and iron. In order to inform ourselves in regard to the character of the soils in the field stations, and also to show farmers the essential character of plant food, analytical or deficiency plots were formed at each field station. The results of last year were reported, and these indicated that full growth was interfered with only when nitrogen, or phosphorus, or potash

was omitted. The omission of sulphur and of magnesia was attended with little or no decrease in crop. The commercial import of this subject may not be obvious to the general reader. If, however, sulphur be not essential, not only may we avoid using manures injurious to plants by containing sulphuric acid, but we need not insure the presence of that substance by adding sulphate of lime or sulphate of magnesia. Further, if so minute traces of magnesia and lime as are in Hassocks soil be sufficient, we need not apply these substances, but safely trust to the soil and to impurities in manure to provide all that is required. Practically, therefore, manuring would be limited to the provision of three substances, viz., nitrogen, phosphorus and potassium (potash). It will, no doubt, be understood that this doctrine implies no disregard of the beneficial action of lime, but would cause its action to be regarded and due chiefly to mechanical and decomposing action on the soil."

The following are the proposals Mr. Jamieson makes for 1883:

1. To continue the analytical plot at the field stations. The longer they are continued, the more decided should be the differences in the crops from the various plots, and the more reliable the information.
2. That the root plots should be cropped with mangolds, without manure, in order to show the lasting effects of the different manures already applied.
3. That wheat should again be grown with manure on the wheat plots of last season, in order to show whether profitable crops may be grown in soil from which heavy crops have been got, by treating with what are deemed soil-exhausting manures.
4. To ascertain quantity, and as far as possible, the quality of the produce from various grass seeds. A large number of new plots have been opened up, and sown with this end in view. The various grass seeds to be sown in spring.
5. To continue and develop the experiments at Hassocks Gate, mainly to further elucidate the question of the mineral ingredients absolutely essential to plant growth.

THE Victorian Government statist has issued his quarterly abstract, showing the estimated population of Victoria on December 31, 1882. The number of births during the year was 26,741; the arrivals by sea were 59,401; making a total increase of 86,145. The deaths were 13,630: the departures by sea, 48,524; making the total decrease of 62,154. The net increase during the year was thus 23,991. The population, on December 31, 1881, was 461,222 males, and 418,010 females; and on December 31, 1882, 477,507 males, and 428,710 females, or a total of 906,217. The apparent increase of population in 1882 (23,991) was greater than that in 1881 by 1,826, and although less than in 1880—the Exhibition year—by 2,160; was greater than in any other year since 1871; the increase by excess of recorded arrivals by sea over recorded departures by sea (10,880) was exceeded in 1880 by 780; but was greater by 3,558 than the same excess in 1881, and was also above that in any other year since 1870; the increase by excess of registered births over registered deaths (13,111) was, with the exception of that in 1875, the smallest in the last 14 years.

THE agricultural returns published by the *South Australian Register* show that the late wheat harvest has been the worst ever experienced in South Australia. The total produce was 8,273,000 bushels, giving an average of 4 bushels and 32 lbs. per acre, which is 2 lbs. less than the yield of the preceding year.

THE United States Consul at Auckland, writing on the trade and industry of New Zealand, says it is estimated that the forests of New Zealand cover an area of not less than 20,000,000 acres, the forests on the Crown lands alone being estimated at 10,000,000 acres; about 5,000,000 acres are the private property of the white or European population, and the remainder of the Maori, or native inhabitants. Among the many descriptions of timber grown, the *kauri* pine is considered one of the most valuable; it is found only in the province of Auckland, and in that district it does not exist further south than the East Cape, and like the cedar, it is confined to the vicinity of the sea. The *kauri* forests cover about 60,000 acres of crown land, and about 120,000 acres of private property.

The trees often grow to a height of 200 feet, and measure from 12 to 30 feet in circumference; they are discovered occasionally with a rugged surface, and on being cut, the grain is found to be mottled. The kauri is exported largely in what is called "junk," the logs being squared with an axe, thus wasting a quantity of good timber. The annual output of kauri timber is about 110,000,000 feet, and the highest estimate of the amount of timber left in the kauri forests is 23,000,000 feet. The subject of conserving the kauri forests is at the present time attracting considerable attention throughout the colony, not only on account of the excellent timber it produces, but on account of the gum which exudes from the tree, and which for many years has formed the most valuable article of export of the province of Auckland. Next to the kauri, the *Kahikatea*, a species of white pine, is the most highly prized. It grows in the low lands in the vicinity of rivers. There is an immense forest of these trees between the Thames and Piako rivers, thirty or forty miles in length, and several miles in breadth. The *kahikatea* is found in the kauri districts, and but little attention is paid to it, notwithstanding the fact that its value, as a timber for building purposes, is becoming very generally known. *Totara*, a hard close-grained wood, is largely used in the south of New Zealand; it is a good sound timber, reddish in colour, and very durable. It is largely used for telegraph poles, and has attracted much attention during the last few years from the fact that it will withstand the disastrous ravages of the *Teredo navalis*, a sea parasite, common to the islands of the Western Pacific. *Pariri* is another hard durable wood; it is largely used in the construction of railway trucks. This wood is said to make excellent furniture, though it is not much used for this purpose. Another very valuable timber tree is the *Maire*, a native olive. It is hard, oily, and close-grained. *Pohutakawa* is a coast variety of a tree used for ship-building. This tree is one of the best known in New Zealand; large branches of it, bearing beautiful brush-like red flowers, are everywhere cut at Christmas for the purpose of decorating houses and churches. It affects rocky cliffs, its leaves are large and thick, of a greenish blue colour on the outside, and the inside perfectly white. The trunk is gnarled and twisted in every direction. The inland variety of this tree is called the "rata," and there is a curious growth clinging to the rata, which has been the cause of much speculation among scientific men. It has not yet been decided whether it is deposited as a seed in the forks of high trees, or whether it creeps up from the ground like the ivy. It is found as a mere thread on the trunk, and thickens and sends out side shoots, and intertwines, as the ivy intertwines the oak. In time, the large tree perishes, and the frail slender growth stands alone with its arms outstretched, embracing the circular space where its supporter formerly stood, and the stems that have grown around and about the same supporting tree will unite and form one hollow rata tree, with bark inside and out. Among the other better-known New Zealand trees may be mentioned the *Kawaka*, *Matai*, *Tenekaha*, *Rarirai*, *Manoas*, *Kouhai*, *Miro*, *Hinaiu*, *Titoki*, *Horo-pito*, *Manuka*, *Pahautea*, *Tawai*. The number of saw-mills in the colony is steadily increasing, and it is estimated that there are 250 at present in operation, while in 1879 there was only 204; and at that time Mr. Levy, in a report to the New Zealand Government, estimated the yearly supply from each of these mills at 1,000,000 superficial feet, or about 200,000,000 superficial feet as the total annual product. It appears, from the statistical returns of the New Zealand trade, that the value of timber exported in 1881 amounted to £77,000, against £53,600 in 1880.

PLANTAIN CULTIVATION FOR INDIA.

(Communicated.)

CLIMATE.

THE real climate for plantain is the one which has moderate cold and heat; and which has the atmospheric air loaded with moisture,—in other words, *humid climate*. In such a climate plantain will grow, shoot and fruit very freely; and mature its fruit altogether well. Much cold helps to retard and make imperfect the processes of involution and evolution, thereby stunting the growth of stem, leaves, and fruit; and partially or wholly, according to the degree of cold, withholding the maturity of the fruit. On the other hand, much heat, by the rapid exhalation of moisture, so greatly exhausts the plant that it has scarcely strength left to grow, consequently gets perfectly scorched of the leaves and outer

layers of the stem-sheathes. In illustration of this subject I might here add, in many parts of India, such as North-West Provinces, Oudh, and the Punjab, most parts of these provinces, where the summer season is fearfully hot, I have observed the plantain so severely suffer during this season that during the rains, so to speak, it has to commence life afresh; and when the winter sets in, growth being imperfect, it has no power to muster sufficient strength to send out fruit-spikes: after the winter it has again to embrace the summer season which, as said above, serves only to destroy it,—thus, I have seen plantain growing and suffering, again growing and again suffering for a number of years, and never, or very imperfectly fruiting, which fruit never fully developing and ripening, but getting either scorched (if in the summer) or stunted (if in the winter).

TIME OF PLANTING.

The best and most inexpensive season for planting plantain is when the rains have thoroughly set in, i.e., from the end of June to end of August. This applies to drier parts of India, such as N.-W. Provinces, Oudh, the Punjab, Central Provinces, &c., but in Bengal, Assam, and British Burmah, in addition to these two or two-and-a-half months, February to April will be equally suitable to plantain planting. Being altogether a succulent plant, having much water in its composition, the rainy season has peculiar advantages for the growth of this plant, which no other season, in Upper Western India, in particular, can supply. In Lucknow and Sitapore, both Oudh districts, I have planted plantain in all parts of the year, and grown it successfully, but by resorting to the costly means of artificial irrigation. I would, therefore, in point of economy and on chemico-physiological grounds, recommend the rainy season to be the best for planting in places wanting in the natural advantages of humidity in the soil of Bengal, Assam, and British Burmah.

GEOGRAPHICAL DISTRIBUTION.

Plants of the *N. O. musaceae* are natives of various parts of the world; but all of them, on close examination, will be found to flourish under the same physical conditions of the atmospheric air and soil. The following is the natural geographical distributive scheme of all important cultivated edible species of the plantain and banana order as established by the researches of Professor Baron F. von Mueller, K.C.M.G., M.D., Ph.D., F.R.S. The wording and arrangement are my own; but the subject-matter (from a. to g.) partly belongs to this distinguished naturalist and doctor, and partly to various eminent botanical authorities of older times.

(a.) *Musa Cavendishii*.—Native of China; has been translated to the South Sea Islands, where it is now extensively grown. *M. Cavendishii* has been found to succeed in Madeira and Florida (artificial).

(b.) *Musa paradisiaca*.—India is the native habitat of this most extensively cultivated species, which is said to have one hundred varieties.

(c.) *Musa sapientum*.—Insular India, extending to the Indian Archipelagoes.

(d.) *Musa troglodytarum*.—Older botanists mention its nativity to be in India. Baron Mueller, however, has ascertained it, in addition to India, to be indigenous to the Fiji and other Islands of the Pacific Ocean.

(e.) *Musa simiarum*.—Indigenous to Malacca as far as the Sunda Islands. This plantain, with its varieties, fifty in number, are also to be found in the Indian Archipelagoes.

(f.) *Musa Livingstonia*.—Native of African mountains of Sofala, Mozambique, and the Niger regions.

(g.) *Musa ensata*.—This plantain, the most magnificent of the order, is a native of the mountains of Sofala to Abyssinia in North Africa. I may add it is unknown in India, the masses of the people, existing perhaps in the Botanical gardens. Very eligible for introduction in India. The edible part of this plant is the inner stem.

(h.) *Musa corniculata*.—Native of Insular India.

SOIL.

Loamy soil of the calcareous order, of the species having more *humus* and less *lime*.

COMPOSITION OF SOIL.

| | | | |
|-------|-----|-----|-----------|
| Clay | ... | ... | 40 parts. |
| Lime | ... | ... | 3 " |
| Humus | ... | ... | 5 " |
| Sand | ... | ... | 52 " |
| | | | 100 " |

Plantain all grow in any soil, even in the most sandy. In such a soil, in the Lucknow Agri-Horticultural Gardens, many species and varieties of plantain are growing; but are productive of bad results, since they neither fruit well nor are the fruits so palatable and nutritious as those of Lower Bengal, Burmah, China, and other places. Plantain requires good percentage of clay and humus in the soil without which, as a plantain grower, I can, from personal observations, testify that it is useless to cultivate this plant; especially where quality as well as quantity of the fruit are objects points undeniably every cultivator do and should aim at. Much lime in the soil is bad for plantain; in moderate quantity, it is highly beneficial. This I say from my failing to obtain fruit from plants grown on highly calcareous soil, in which slender stem and stunted appearance (sure signs of not fruiting) of plants of three years' standing, were the results. During these three years they never fruited; had, therefore, to be rooted up. But in soil having less lime, more humus, good percentage of clay and sufficient sand to keep the soil loose and friable, I have in six months, calculated from the time of planting, succeeded to grow off shoots two feet high of the tall varieties into almost full-grown size, measuring twelve feet high to the apex of the leaf, ready to throw out fruit-spike by the end of the rainy season. The off-shoots were planted in February, and the above height acquired by the end of July.

CHEMISTRY OF THE PLANTAIN PLANT.

The centennial composition of the plantain plant in a green or fresh undried state will appear from the following table, being the mean of 7 analyses:

| | Water. | Organic matter other than water. | Inorganic matter or ash. | Total. |
|-----------------------|--------|----------------------------------|--------------------------|--------|
| Leaves | 80.15 | 15.90 | 3.95 | 100 |
| Stem | 81.5 | 14.95 | 3.55 | 100 |
| Fruit, including rind | 75.58 | 21.17 | 3.25 | 100 |
| Total | 237.23 | 52.02 | 10.75 | 300 |

Centennial chemical composition of the inorganic or ash portion, being mean of 7 analyses:—

| | Leaves. | Stem. | Fruit including rind. |
|---|---------|--------|-----------------------|
| Oxide of Iron | ... | 1.00 | 1.86 |
| Oxide of potassium | 20.59 | 18.30 | 20.15 |
| Chloride of potassium | 15.43 | 14.43 | 10.52 |
| Chloride of sodium | 7.58 | 5.25 | 3.75 |
| Oxide of calcium | 10.97 | 11.25 | 15.26 |
| Oxide of magnesium | 2.66 | 3.28 | 4.75 |
| Phosphoric acid | 2.95 | 8.52 | 25.96 |
| Carbonic acid | 7.27 | 5.07 | 2.05 |
| Sulphuric acid | 1.76 | 1.52 | 5.15 |
| Oxide of silicon | 25.54 | 25.15 | 7.65 |
| Waste, &c., earthy matter, or oxide of aluminum | 5.25 | 6.23 | 2.90 |
| Total | 100.00 | 100.00 | 100.00 |

The foregoing tables should be taken as approximate data of the chemical constituents of all species and varieties of the plantain plant. The tables have been constructed from analyses of seven different edible varieties of plantain in general cultivation in Bengal, and from there disseminated in other parts of India.

The organic principles of the plantain fruit are starch in abundance, and protein compounds, hence, the fruit is nitrogenous and excellent food. The pith of the stem and root bulb contain starch. These principles exist in different proportions in the same plant, and in different species and varieties, cultivation and fertilizing matters in the soil having also much influence in augmenting or lessening them.

PARTITIONING, TRENCHING, AND MANURING OF SOIL.

The soil, measuring 660' x 66', or one acre, should be partitioned off breadthwise into 3 partitions by 2 water channels, allowing 2' for each water channel; and having trenches 4' each wide with intervening space of 6' from border of trench to trench:—thus, we will have 660 ÷ (6' intervening space from trench + 4' width of each trench) = 66 trenches in each partition and (66' 66' ÷ (2' space occupied by one water channel + 2' space for the other water channel) = 16—6' = length of each trench, or length of each trench. These trenches, 330 in number, 26—8 long and 4' broad each, should be marked and prepared, two months before the planting time by digging 3' deep, one foot of earth of which should be thrown on two side-spaces on both sides of each trench. This finished, suitable manure or compost should be thrown in the trenches, thoroughly incorporated with the soil, and irrigated with liquid manure, if available, or with water. The irrigation is required for inducing physical changes in the soil by which the manure and soil are rendered eminently fit as plant-food ingredients. It might be omitted if natural irrigation by the fall of rain be available, otherwise it is indispensable.

UTILIZATION OF BLANK SPACES.

In the first and subsequent years of plantain planting much space is available, both in the trenches and in the space intervening them, which certainly can be utilized in various ways, for raising of seedlings and cuttings of various kinds requiring sheltered positions, and for placing pots, &c., containing stocks for budding, inarching, and grafting.

SELECTIONS OF OFF-SHOOTS, PLANTING, AND THE NUMBER REQUIRED FOR PLANTING AN ACRE.

The best size of off-shoots for planting is 2' up to the apex of the highest leaf calculated from above the bulb. Smaller plants do not succeed so well being so very tender, and larger ones suffer from transplantation owing to the delay of springing out of fresh roots without which the plant cannot establish itself, also for the rapid and great exhalation of water from the stem and leaves.

Young plantain plants should be planted one foot deep, in the middle of the trench, preceded by a hoeing of the soil if possible, six feet apart from plant to plant in the same trench, and immediately irrigated. But it would be very desirable to so time the planting time, as to fall on rainy day or days, and at the time when it is fast raining; as the planting at this time would ensure economy and remarkably facilitate the establishment and growth of the plants.

From what I have said in this and previous headings it will appear there are 4 plants in each trench and as there are 330 such trenches in the acre, the number of plants per acre will be 330 x 4 = 1,320 plants, each of which eventually growing into a group of from 6 to 15 plants of various sizes.

IRRIGATION.

Where natural advantage of humidity of the soil does not exist, irrigation for plantain is very important. In such places the soil (trenches only), in which plantain plants are growing, requires to be constantly flooded with water by artificial means, in the summer and winter; and during the rains also if the falls of rain be at long intervals and scanty. When, however, the fruit-spikes have been sent out, total withdrawal, or in moderate quantity according to the nature of the soil and condition of the season, of irrigation should be made, to allow the sap to concentrate for the formation of new substances for the fruit, to be again applied when the fruits have established themselves on the spike.

AFTER-CULTURE.

This consists in the elimination of weeds from the trenches, hoeing round the plants, not less than six inches deep, and manuring once a year during the rainy weather.

TRANSPLANTATION.

Every third year plantain plants require to be rooted up, the root-bulbs deprived of the stems, separated, and only the healthy off-shoots or young plants planted out in the same trench which has been well hoed and manured. By doing this fresh vigour is imparted to the young plants which had to

struggle for existence between the intermining net-work of root of old plants, ripened, fruited and removed.

HARVESTING AND STORING OF FRUIT-SPIKES.

When one or two fruits on the spike have ripened, the spike should be removed from the plant, and the plant, also. The fruit-spike should be stored, i.e., hung from the ceilings, in a warm air-tight room, to allow all the fruits to ripen.

YIELD.

The yield of plantain plant is very various owing to various causes. Again, two varieties or species not producing alike in the number, size, and quality of its fruit. The minimum, per spike or plant, is 80 fruits, and the maximum 500 fruits, of various sizes.

O. L. BRYCE,

Agri-Analytical Chemist,

Late Supdt., Agri-Hortl. Socy. of Oudh Gardens.

OFFICIAL PAPERS.

ALOE FIBRE.

THE following translation of extracts from Mons. Evonor de Chazal's lecture regarding aloe fibre and the recent improvements effected in the process of extraction, read before the Members of the Chamber of Agriculture at St. Antoine, in the Mauritius, on the 19th January 1882, has been printed by the Madras Government:—

The attention of the Chamber of Agriculture of Mauritius has been lately drawn to a new industry which is already being carried on, on a large scale, in that colony, viz., the extraction of aloe fibre. A method has been lately discovered of extracting the fibre of the plant in question in a most economical way, and this discovery has carried a new element of prosperity in the colony. The first idea had been to employ, for the extraction of the fibre, the mills used for crushing the sugar-cane, and on this subject Mr. Cosigny writes as follows in his remarkable work entitled "Means of improvements proposed to the inhabitants of colonies." In the *pita* aloe, the Negroes, to their great advantage, find the material necessary for making cords and ropes which are useful in the Colonies, where they are substituted for hemp and flax ropes. This fibre serves to make up all that is necessary to harness animals of drought and burden. Threads of *pita* aloe are employed in Manilla for making pretty strong stuffs which are dyed in blue, and with which the inhabitants clothe themselves. I do not know whether at St. Domingo, or even at Manilla, they steep the leaves of aloe to separate the threads. This operation does not seem necessary when the leaves are employed for the making of ropes, but in the manufacture of stuffs, the steeping process would make the threads softer and stronger. It is apparently for want of this operation that the fibre is generally so stiff; the juice of the leaves should, therefore, be squeezed out by being passed through the cylinders of a sugar-mill; afterwards they should be left to soak for a few days in stagnant water, which, aided by fermentation, would dissolve the gum contained in them, after which they might be washed in running water. We do not make use in the Isle of France and Bourbon of our *pita* aloe, which grow very readily in all sorts of soil without any cultivation. Besides the *pita* aloe, we should also cultivate the aloe of Socotra to obtain the gummy-resinous extract which they contain, which has a great consumption in India and in Europe. The Dutch Colonists practise this industry at the Cape of Good Hope. Besides hemp and flax, we have in our Eastern Colonies several plants which produce fibre. I shall mention especially the two species of aloe which are to be found in the Isle of France and Bourbon and which grow in the most dry and unproductive localities. Starting on the assumption that the leaves should be bruised in order that they may be more easily steeped, they at first made use of sugar-mills, but it was soon found out that the cylinders cut the threads, and the system was abandoned. So was the steeping owing to the want of water. Later on, they made use of mechanical beaters imitating the hand of man. At last the scraper was introduced, the discovery of which is claimed by several inventors and cannot possibly be attributed to any one in particular. The present mode of extraction consists of a pulley or wheel nearly as big as a common cart-wheel. This wheel is surmounted throughout its circumference by conical, or scraper, incrusts in the wood, and kept firm by means of pegs. There are 14 or 15 of these upon the whole circumference. If the wheel is five feet in diameter with about 15 scrapers, so arranged, it follows that there will be a space of one foot between each scraper. This pulley which is the essential part of the apparatus, is fixed upon a stand, and is put in motion like every apparatus of this kind by a propeller. Imagine now, in front of this pulley, which turns four or five hundred times per minute, a table like that which is found in front of cane-mills, only narrower, and at this table a piece of wood against which the scrapers of the pulley press. This piece of wood is called the *servante*. It is regulated by a screw fixed behind, and

plays a very important part in the working of the apparatus, for, according as it is too tight or too loose, the fibres are either out, or not sufficiently scraped. There ought to be between this *servante* and the scrapers a very carefully-defined space, as every thing depends on the way in which the *servante* is regulated.

You have now before you what manufacturers of fibres have agreed to call the *grattieuse* (scraper). This *grattieuse* is not perfect, but very nearly so, and, on seeing it work, one is surprised to observe what little power it requires and into what small particles it breaks the fibres. The man who works it stands in front; he shoves the leaves rapidly one after another point fore. The leaf, carried away by the rotation of the fluted cylinders which are under the hand of the workman, is scraped along its greatest length and returns the same way in the state of fibre, with the exception of a small portion, varying from 6 inches to 1 foot, which is called the *talon* or the trunk end of the leaf, that is to say, the thick end which adheres to the trunk. What shall they do with this *talon*? Must it be cut as recommended by some, or must it be scraped? But this second operation cannot be performed with the same apparatus. Which apparatus then should be adopted? We now come to a new apparatus called the *casse-tête*. It is composed of a wheel identically similar to that of the *grattieuse* and surmounted like it with the scrapers, with this difference, however, that, instead of turning against a fixed *servante*, it turns on a movable wooden slipper 18 inches long which forms a lever or pedal. It has already been said that, after having passed the *grattieuse*, the aloe leaf, reduced to fibre for the greatest part of its length, still retains a thick end, called the *talon*. The workman who performs the second operation fastens the scraped portion of the leaves by bundles of 5 or 6 at a time to a hook which projects from the wooden slipper open under his feet; then, placing his foot on the pedal, he sets it in motion from bottom to top in bringing it near the pulley, so that the scrapers, turning with the rapidly already mentioned, take away what remains of the non-scraped portion of the leaves, viz., the *talon*.

The aloe, all varieties of which are not equally useful to our industry, is composed of a trunk around which are grouped spirally leaves varying in length from 3 to 7 inches. When looking at the leaves attentively, we observe that the part which touches the trunk is the fleshy part, the heaviest and the strongest. The leaf ends in a point with a solid thorn. All fibres necessarily come from the trunk, but they all do not reach to a terminal point as may be ascertained by tearing a leaf lengthwise. Those of the middle alone reach so far, those of the sides stop midway. The consequence is that when a leaf of the aloe is cut at any distance whatever from the trunk, such distance varying from 6 inches to one foot, all the fibres have been cut at one and the same point. If we now suppose that it is this end that will be first scraped, all the fibres will necessarily be secured at their terminal point, when the leaf is turned for a second scraping. But this was not the way in which they went to work formerly. They at first placed the leaf before the apparatus at its terminal point; then when three-fourths were scraped, it was turned back again to place the *talon* before the *casse-tête*. In this second operation the longest fibres alone are retained at the hook; the others are carried away by the rapid rotation of the pulley, and are lost so that the result of the second operation will be that after having scraped a *talon* of 6 inches or 1 foot in length, it will have spoilt at the same time a portion of the work turned out by the first machine by taking away the fibres already extracted by it, because they were not long enough to be secured in the hook. But in the new process I have described, this defect is remedied to a great extent, and the chief improvement in it is the doing away with the *casse-tête*. It is original in this way, viz., that the *talon* of the leaf is scraped before the point. The *servante* is considerably used in the improved system; its regulation, the new form that has been given to it, the new materials with which it is made, constitute as many improvements in the manner of presenting the leaf of the apparatus and contribute to increase its yield.

It is generally admitted that the leaves of aloe give an average yield of 2 per cent, that is to say, not 2 lb. of fibre for 100 lbs. of leaves, but 2 lb. of fibre for 100 leaves. But since the recent improvements the same leaf gives a minimum yield of 3 per cent, or often more, without increased expenditure, but on the contrary with infinitely less propelling power. The following is the result of experiments made at "Palmyra" with the new apparatus:—

Firstly.—Fifty leaves of average size, 4 feet long, weighing 56 lbs., produced lbs. 1.75 of dry fibres, or lbs. 3.50 per 100 leaves, or lb 3.12 per 100 lbs.

Secondly.—Five leaves of malgache aloe, 7 feet long, weighing 24 lb., produced lb. 0.49, or lb. 9.80 per 100 leaves, or lb. 2.03 per 100 lb.

At Mount "Cholsey," in the apparatus of Mr. Cazotet, 25 leaves, weighing 42 lbs., produced lbs. 1.28 of dry fibre, or lbs. 3.12 per 100 leaves, or lbs. 3.05 per 100 lbs. The present average realized by Mr. Cazotet with the new apparatus is $3\frac{1}{2}$ to $3\frac{3}{4}$ lbs. per 100 leaves. In other places they have realised up to 4.16 lbs. per 100 leaves on a week's average work. These figures are much above those realized hitherto, since they represent an average of from 3 to $3\frac{1}{2}$ lbs. of dry fibre per 100 leaves, whilst with the old apparatus the result was hardly 2 per cent.

Dr. J. Forbes Royle, in his work entitled "The fibrous plants of India suitable for cordage, clothing, and paper," says:—The *Agave* (aloe), a native of America, has become so naturalized as to appear to be indigenous in Africa, in India, and the South of Spain. The *Agave* plants, to which the name of American aloe is so frequently applied, resemble the true aloe in their sword-shaped leaves with parallel veins, which however grow to a gigantic size—that is, from 8 to 10 feet in length—in a cluster from the root with their margins usually armed with short thorns and their points with a hard thorn. This makes these plants so

useful in the construction of hedges and enclosures—a use to which they are applied in Italy and Sicily. The plants come to perfection in about 3 years, though they do not flower for 8, and sometimes perhaps not for 20 years, when they throw up a flower-like stalk. It is the leaves of these plants which abound in fibres of great length and of considerable strength. Being also tough and durable, they are separated for the purpose of making string and rope found to be of great value. The juice which flows from them is sometimes substituted for soap. The fibres of these *Agaves* are converted into cordage in Mexico, and this cordage is often used in mines and on boardship.

Humboldt gives a description of the bridge on the river "Chambo" at "Quito" about 131 feet long, the principal ropes of which, about 4 inches in diameter, were made from aloe fibres. It is said that in the West Indies the Negroes make ropes, fishing nets, and hammocks out of the aloe fibres. The preparation is as follows:—At first the longest leaves of the plant are cut, and afterwards are scraped with an iron bar which is held by both hands until the whole of the juice and the pulp are removed, and there remains only the thread. Steedman says that the fibre is like silk, and that ropes made from it are considered in England as good as any other, but that they rot more easily in water.

In Portugal this fibre is called "threads of Pita," and is used for various purposes. In Spain it is called "Pita," and, as the plant is abundant in that country, it serves for making ropes of all sizes on a large scale.
